Transition systems

Transition systems

Formalization of the dynamics of the world/application

Definition

A **transition system** is $\langle S, I, \{a_1, \dots, a_n\}, G \rangle$ where

- S is a finite set of **states** (the **state space**),
- $I \subseteq S$ is a finite set of **initial states**,
- every action $a_i \subseteq S \times S$ is a binary relation on S ,
- $G \subseteq S$ is a finite set of **goal states**.

Definition

An action a is **applicable** in a state s if $sa s'$ for at least one state s' .

Transition systems

Deterministic transition systems

A transition system is **deterministic** if there is only **one initial state** and **all actions are deterministic**. Hence all future states of the world are completely predictable.

Definition

A **deterministic transition system** is $\langle S, I, O, G \rangle$ where

- S is a finite set of **states** (the **state space**),
- $I \in S$ is **a state**,
- actions $a \in O$ (with $a \subseteq S \times S$) are **partial functions**,
- $G \subseteq S$ is a finite set of **goal states**.

Successor state wrt. an action

Given a state s and an action A so that a is applicable in s , the **successor state** of s with respect to a is s' such that $sa s'$, denoted by $s' = \text{app}_a(s)$.

Blocks world

The rules of the game

Location on the table does not matter

Location on a block does not matter

At most one block on/under a block is allowed

Blocks world

The transition graph for three blocks

Blocks world

Properties

blocks	states
1	1
2	3
3	13
4	73
5	501
6	4051
7	37633
8	394353
9	4596553
10	58941091

- Finding a solution is polynomial time in the number of blocks (move everything onto the table and then construct the goal configuration)
- Finding a shortest solution is NP-complete (for a compact description of the problem).

Deterministic planning: plans

Definition

A **plan** for $\langle S, I, O, G \rangle$ is a sequence $\pi = o_1, \dots, o_n$ of operators such that $o_1, \dots, o_n \in O$ and s_0, \dots, s_n is a sequence of states (the **execution** of π) so that

- $s_0 = I$,
- $s_i = \text{app}_{o_i}(s_{i-1})$ for every $i \in \{1, \dots, n\}$, and
- $s_n \in G$.

This can be equivalently expressed as

$$\text{app}_{o_n}(\text{app}_{o_{n-1}}(\dots \text{app}_{o_1}(I) \dots)) \in G$$

Transition relations as matrices

- If there are n states, each action (a binary relation) corresponds to an $n \times n$ matrix: Element at row i and column j is 1 if the action maps state i to state j , and 0 otherwise. For deterministic actions there is at most one non-zero element in each row.
- Matrix multiplication corresponds to **sequential composition**: taking action M_1 followed by action M_2 is the product M_1M_2 . (This also corresponds to the **join** of the relations.)
- The unit matrix $I_{n \times n}$ is the NO-OP action: every state is mapped to itself.

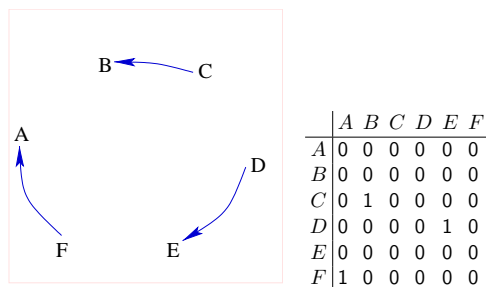

Example

Example

Example

Sum matrix $M_R + M_G + M_B$

Representing one-step reachability by any of the component actions

We use addition $0 + 0 = 0$ and $b + b' = 1$ if $b = 1$ or $b' = 1$.

Reachability

Let M be the $n \times n$ matrix that is the (Boolean) sum of the matrices of the individual actions. Define

$$\begin{aligned}
 R_0 &= I_{n \times n} \\
 R_1 &= I_{n \times n} + M \\
 R_2 &= I_{n \times n} + M + M^2 \\
 R_3 &= I_{n \times n} + M + M^2 + M^3 \\
 &\vdots
 \end{aligned}$$

R_i represents reachability by i actions or less. If s' is reachable from s , then it is reachable with $\leq n - 1$ actions: $R_{n-1} = R_n$.

Sequential composition as matrix multiplication

$$\begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 1 & 0 \end{pmatrix} \times \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 1 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 1 & 0 \\ 1 & 1 & 1 & 0 & 1 & 1 \\ 0 & 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 0 \end{pmatrix}$$

E is reachable from B by two actions because
 F is reachable from B by one action and
 E is reachable from F by one action.

Reachability: example, M_R

Reachability: example, $M_R + M_R^2$

Reachability: example, $M_R + M_R^2 + M_R^3 + I_{6 \times 6}$

A simple planning algorithm

- ▶ We next present a simple planning algorithm based on computing **distances** in the transition graph.
- ▶ The algorithm finds shortest paths **less efficiently** than Dijkstra's algorithm; we present the algorithm because we later will use it as a basis of an algorithm that is applicable to much bigger state spaces than Dijkstra's algorithm directly.

A simple planning algorithm

1. Compute the matrices $R_0, R_1, R_2, \dots, R_n$ representing reachability with $0, 1, 2, \dots, n$ steps with all actions.
2. Find the smallest i such that a goal state s_g is reachable from the initial state according to R_i .
3. Find an action (the last action of the plan) by which s_g is reached with one step from a state $s_{g'}$ that is reachable from the initial state according to R_{i-1} .
4. Repeat the last step, now viewing $s_{g'}$ as the goal state with distance $i - 1$.

Reachability: example, $M_R + M_R^2 + M_R^3$

Relations and sets as matrices

Row vectors as sets of states

Row vectors S represent sets.

SM is the set of states reachable from S by M .

$$\begin{pmatrix} 1 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}^T \times \begin{pmatrix} 1 & 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 0 & 1 & 1 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ 0 \\ 1 \\ 1 \\ 1 \end{pmatrix}^T$$

A simple planning algorithm

Idea

Example

$$\begin{matrix} & \begin{matrix} A & B & C & D \end{matrix} \\ \begin{matrix} A \\ B \\ C \\ D \end{matrix} & \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix} \end{matrix} + \begin{matrix} & \begin{matrix} A & B & C & D \end{matrix} \\ \begin{matrix} A \\ B \\ C \\ D \end{matrix} & \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \end{matrix} = \begin{matrix} & \begin{matrix} A & B & C & D \end{matrix} \\ \begin{matrix} A \\ B \\ C \\ D \end{matrix} & \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix} \end{matrix}$$

Example

	A	B	C	D		A	B	C	D	
$R_0 =$	A	1	0	0	0	A	1	1	0	0
	B	0	1	0	0	B	0	1	1	0
	C	0	0	1	0	C	1	0	1	1
	D	0	0	0	1	D	0	0	0	1

	A	B	C	D		A	B	C	D	
$R_2 =$	A	1	1	1	0	A	1	1	1	1
	B	1	1	1	1	B	1	1	1	1
	C	1	1	1	1	C	1	1	1	1
	D	0	0	0	1	D	0	0	0	1

State variables

- The state of the world is described in terms of a **finite set of finite-valued** state variables.

Example

HOUR : {0, ..., 23} = 13
 MINUTE : {0, ..., 59} = 55
 LOCATION : { 51, 52, 82, 101, 102 } = 101
 WEATHER : { sunny, cloudy, rainy } = cloudy
 HOLIDAY : { T, F } = F

- Any n -valued state variable can be replaced by $\lceil \log_2 n \rceil$ Boolean (2-valued) state variables.
- Actions change the values of the state variables.

Blocks world with Boolean state variables

Example

$s(AonB)=0$ $s(AonC)=0$ $s(AonTABLE)=1$
 $s(BonA)=1$ $s(BonC)=0$ $s(BonTABLE)=0$
 $s(ConA)=0$ $s(ConB)=0$ $s(ConTABLE)=1$

Propositional logic

Let A be a set of atomic propositions (\sim state variables.)

- For all $a \in A$, a is a propositional formula.
- If ϕ is a propositional formula, then so is $\neg\phi$.
- If ϕ and ϕ' are propositional formulae, then so is $\phi \vee \phi'$.
- If ϕ and ϕ' are propositional formulae, then so is $\phi \wedge \phi'$.
- The symbols \perp and \top are propositional formulae.

The implication $\phi \rightarrow \phi'$ is an abbreviation for $\neg\phi \vee \phi'$.
 The equivalence $\phi \leftrightarrow \phi'$ is an abbreviation for $(\phi \rightarrow \phi') \wedge (\phi' \rightarrow \phi)$.

Succinct representation of transition systems

- More **compact** representation of actions than as relations is often
 - possible** because of symmetries and other regularities,
 - unavoidable** because the relations are too big.
- Represent different aspects of the world in terms of different **state variables**. \implies A state is a **valuation of state variables**.
- Represent actions in terms of changes to the state variables.

Blocks world with state variables

State variables:

LOCATIONofA : { B, C, TABLE }
 LOCATIONofB : { A, C, TABLE }
 LOCATIONofC : { A, B, TABLE }

Example

$s(\text{LOCATIONofA}) = \text{TABLE}$
 $s(\text{LOCATIONofB}) = A$
 $s(\text{LOCATIONofC}) = \text{TABLE}$

Not all valuations correspond to an intended blocks world state, e.g. s such that $s(\text{LOCATIONofA}) = B$ and $s(\text{LOCATIONofB}) = A$.

Logical representations of state sets

- n state variables with m values induce a state space consisting of m^n states (2^n states for n Boolean state variables).
- A language for talking about *sets of states (valuations of state variables)* is the **propositional logic**.
- Logical connectives correspond to set-theoretical operations.
- Logical relations correspond to set-theoretical relations.

Propositional logic

Valuations and truth

A **valuation** of A is a function $v : A \rightarrow \{0, 1\}$. Define the notation $v \models \phi$ for valuations v and formulae ϕ by

- $v \models a$ if and only if $v(a) = 1$, for $a \in A$.
- $v \models \neg\phi$ if and only if $v \not\models \phi$
- $v \models \phi \vee \phi'$ if and only if $v \models \phi$ or $v \models \phi'$
- $v \models \phi \wedge \phi'$ if and only if $v \models \phi$ and $v \models \phi'$
- $v \models \top$
- $v \not\models \perp$

Propositional logic

Some terminology

- ▶ A propositional formula ϕ is **satisfiable** if there is at least one valuation v so that $v \models \phi$. Otherwise it is **unsatisfiable**.
- ▶ A propositional formula ϕ is **valid** or a **tautology** if $v \models \phi$ for all valuations v . We write this as $\models \phi$.
- ▶ A propositional formula ϕ is a **logical consequence** of a propositional formula ϕ' , written $\phi' \models \phi$, if $v \models \phi$ for all valuations v such that $v \models \phi'$.
- ▶ A propositional formula that is a proposition a or a negated proposition $\neg a$ for some $a \in A$ is a **literal**.
- ▶ A formula that is a disjunction of literals is a **clause**.

Succinct transition systems Operators

Operators

Actions are represented as **operators** $\langle c, e \rangle$ where

- ▶ c (**the precondition**) is a propositional formula over A describing the set of states in which the action can be taken. (*States in which an arrow starts.*)
- ▶ e (**the effect**) describes the successor states of states in which the action can be taken. (*Where do the arrows go.*)
The description is procedural: how do the values of the state variable change?

(Albert-Ludwigs-Universität Freiburg)

AI Planning

April 13, 2005 35 / 60

Succinct transition systems Operators

Effects

Meaning of conditional effects \triangleright

$c \triangleright e$ means that change e takes place if c is true in the current state.

Example

Increment 4-bit numbers $b_3b_2b_1b_0$.

$$\begin{aligned} &(\neg b_0 \triangleright b_0) \wedge \\ &((\neg b_1 \wedge b_0) \triangleright (b_1 \wedge \neg b_0)) \wedge \\ &((\neg b_2 \wedge b_1 \wedge b_0) \triangleright (b_2 \wedge \neg b_1 \wedge \neg b_0)) \wedge \\ &((\neg b_3 \wedge b_2 \wedge b_1 \wedge b_0) \triangleright (b_3 \wedge \neg b_2 \wedge \neg b_1 \wedge \neg b_0)) \end{aligned}$$

(Albert-Ludwigs-Universität Freiburg)

AI Planning

April 13, 2005 37 / 60

Succinct transition systems Operators

Operators: meaning

Changes caused by an operator

Assign each effect e and state s a set $[e]_s$ of literals as follows.

1. $[a]_s = \{a\}$ and $[\neg a]_s = \{\neg a\}$ for $a \in A$.
2. $[e_1 \wedge \dots \wedge e_n]_s = [e_1]_s \cup \dots \cup [e_n]_s$.
3. $[c \triangleright e]_s = [e]_s$ if $s \models c$ and $[c \triangleright e]_s = \emptyset$ otherwise.

Applicability of an operator

Operator $\langle c, e \rangle$ is **applicable in a state** s iff $s \models c$ and $[e]_s$ is consistent.

(Albert-Ludwigs-Universität Freiburg)

AI Planning

April 13, 2005 39 / 60

Formulae vs. sets

sets	formulae
those $\frac{2^n}{2}$ states in which a is true	$a \in A$
$E \cup F$	$E \vee F$
$E \cap F$	$E \wedge F$
$E \setminus F$ (set difference)	$E \wedge \neg F$
\bar{E} (complement)	$\neg E$
the empty set \emptyset	\perp
the universal set	\top
question about sets	question about formulae
$E \subseteq F?$	$E \models F?$
$E \subset F?$	$E \models F$ and $F \not\models E?$
$E = F?$	$E \models F$ and $F \models E?$

(Albert-Ludwigs-Universität Freiburg)

AI Planning

April 13, 2005 34 / 60

Succinct transition systems Operators

Effects

For deterministic operators

Definition

Effects are then recursively defined as follows.

1. a and $\neg a$ for state variables $a \in A$ are effects.
2. $e_1 \wedge \dots \wedge e_n$ is an effect if e_1, \dots, e_n are effects (the special case with $n = 0$ is the empty conjunction \top .)
3. $c \triangleright e$ is an effect if c is a formula and e is an effect.

Atomic effects a and $\neg a$ are best understood respectively as assignments $a := 1$ and $a := 0$.

(Albert-Ludwigs-Universität Freiburg)

AI Planning

April 13, 2005 36 / 60

Succinct transition systems Operators

Example: operators for blocks world

For convenience we use also state variables $Aclear$, $Bclear$, and $Cclear$ to denote that there is nothing on the block in question.

$$\begin{aligned} &\langle Aclear \wedge AonT \wedge Bclear, AonB \wedge \neg AonT \wedge \neg Bclear \rangle \\ &\langle Aclear \wedge AonT \wedge Cclear, AonC \wedge \neg AonT \wedge \neg Cclear \rangle \\ &\vdots \\ &\langle Aclear \wedge AonB, AonT \wedge \neg AonB \wedge \neg AonC \rangle \\ &\langle Aclear \wedge AonC, AonT \wedge \neg AonB \wedge \neg AonC \rangle \\ &\langle Bclear \wedge BonA, BonT \wedge \neg BonA \wedge Aclear \rangle \\ &\langle Bclear \wedge BonC, BonT \wedge \neg BonC \wedge Cclear \rangle \\ &\vdots \end{aligned}$$

(Albert-Ludwigs-Universität Freiburg)

AI Planning

April 13, 2005 38 / 60

Succinct transition systems Operators

Operators: the successor state of a state

Definition (Successor state)

The **successor state** $app_o(s)$ of s with respect to operator $o = \langle c, e \rangle$ is obtained from s by making literals in $[e]_s$ true.This is defined only if o is applicable in s .

Example

Consider the operator $\langle a, \neg a \wedge (\neg c \triangleright \neg b) \rangle$ and a state s such that

$$s \models a \wedge b \wedge c.$$

The operator is applicable because $s \models a$ and

$$[\neg a \wedge (\neg c \triangleright \neg b)]_s = \{\neg a\}$$

Hence $app_{\langle a, \neg a \wedge (\neg c \triangleright \neg b) \rangle}(s) \models \neg a \wedge b \wedge c$.

(Albert-Ludwigs-Universität Freiburg)

AI Planning

April 13, 2005 39 / 60

(Albert-Ludwigs-Universität Freiburg)

AI Planning

April 13, 2005 40 / 60

Operators

Example

State variables are

$$A = \{a, b, c\}.$$

An operator is

$$\begin{aligned} & ((b \wedge c) \vee (\neg a \wedge b \wedge \neg c) \vee (\neg a \wedge c), \\ & ((b \wedge c) \supset \neg c) \\ & \wedge (\neg b \supset (a \wedge b)) \\ & \wedge (\neg c \supset a)) \end{aligned}$$

The corresponding matrix is

	000	001	010	011	100	101	110	111
000	0	0	0	0	0	0	0	0
001	0	0	0	0	0	0	0	1
010	0	0	0	0	0	0	1	0
011	0	0	1	0	0	0	0	0
100	0	0	0	0	0	0	0	0
101	0	0	0	0	0	0	0	0
110	0	0	0	0	0	0	0	0
111	0	0	0	0	0	0	1	0

Mapping from succinct TS to TS

From every succinct transition system $\langle A, I, O, G \rangle$ we can produce a corresponding transition system $\langle S, I, O', G' \rangle$.

1. S is the set of all valuations of A ,
2. $O' = \{R(o) \mid o \in O\}$ where $R(o) = \{(s, s') \in S \times S \mid s' = \text{app}_o(s)\}$, and
3. $G' = \{s \in S \mid s \models G\}$.

Schematic operators: example

Schematic operator

$$\begin{aligned} x & \in \{\text{car1, car2}\} \\ y_1 & \in \{\text{Freiburg, Strassburg}\}, \\ y_2 & \in \{\text{Freiburg, Strassburg}\}, y_1 \neq y_2 \end{aligned}$$

$$\langle \text{in}(x, y_1), \text{in}(x, y_2) \wedge \neg \text{in}(x, y_1) \rangle$$

corresponds to the operators

$$\begin{aligned} & \langle \text{in}(\text{car1, Freiburg}), \text{in}(\text{car1, Strassburg}) \wedge \neg \text{in}(\text{car1, Freiburg}) \rangle, \\ & \langle \text{in}(\text{car1, Strassburg}), \text{in}(\text{car1, Freiburg}) \wedge \neg \text{in}(\text{car1, Strassburg}) \rangle, \\ & \langle \text{in}(\text{car2, Freiburg}), \text{in}(\text{car2, Strassburg}) \wedge \neg \text{in}(\text{car2, Freiburg}) \rangle, \\ & \langle \text{in}(\text{car2, Strassburg}), \text{in}(\text{car2, Freiburg}) \wedge \neg \text{in}(\text{car2, Strassburg}) \rangle \end{aligned}$$

PDDL: the Planning Domain Description Language

- Used by almost all implemented systems for deterministic planning.
- Supports a language comparable to what we have defined above (including schematic operators and quantification)
- Syntax inspired by the Lisp programming language: e.g. prefix notation for formulae

```
(and (or (on A B) (on A C))
      (or (on B A) (on B C))
      (or (on C A) (on A B)))
```

Succinct transition systems

Deterministic case

Definition

A **succinct deterministic transition system** is $\langle A, I, \{o_1, \dots, o_n\}, G \rangle$ where

- A is a finite set of **state variables**,
- I is an **initial state**,
- every o_i is an operator,
- G is a formula describing the **goal states**.

Schematic operators

- Description of state variables and operators in terms of a given finite set of objects.
- Analogy: propositional logic vs. predicate logic
- Planners take input as schematic operators, and translate them into (ground) operators. This is called **grounding**.

Schematic operators: quantification

Existential quantification (for formulae only)

Finite disjunctions $\phi(a_1) \vee \dots \vee \phi(a_n)$ represented as $\exists x \in \{a_1, \dots, a_n\} \phi(x)$.

Universal quantification (for formulae and effects)

Finite conjunctions $\phi(a_1) \wedge \dots \wedge \phi(a_n)$ represented as $\forall x \in \{a_1, \dots, a_n\} \phi(x)$.

Example

$\exists x \in \{A, B, C\} \text{in}(x, \text{Freiburg})$ is a short-hand for $\text{in}(A, \text{Freiburg}) \vee \text{in}(B, \text{Freiburg}) \vee \text{in}(C, \text{Freiburg})$.

PDDL: domain files

A domain file consists of

- (define (domain DOMAINNAME))
- a :requirements definition (use :adl :typing by default)
- definitions of types (each parameter has a type)
- definitions of predicates
- definitions of operators

Example: blocks world in PDDL

```
(define (domain BLOCKS)
  (:requirements :adl :typing)
  (:types block - object
    blueblock smallblock - block)
  (:predicates (on ?x - smallblock ?y - block)
    (ontable ?x - block)
    (clear ?x - block)
  )
)
```

Succinct transition systems Schematic operators

PDDL: problem files

A problem file consists of

- ▶ (define (problem PROBLEMNAME)
- ▶ declaration of which domain is needed for this problem
- ▶ definitions of objects belonging to each type
- ▶ definition of the initial state (list of state variables initially true)
- ▶ definition of goal states (a formula like operator precondition)

```
(define (problem blocks-10-0)
  (:domain BLOCKS)
  (:objects a b c - smallblock
    d e - block
    f - blueblock)
  (:init (clear a) (clear b) (clear c) (clear d) (clear e)
    (ontable a) (ontable b) (ontable c)
    (ontable d) (ontable e) (ontable f))
  (:goal (and (on a d) (on b e) (on c f))))
