

Execution graphs

- To formalize more complicated planning problems and more complicated forms of plans we define **execution graphs** of a transition system + plan.
- An execution graph describes the possible **states of execution** and the transitions between them.
- For **memoryless plans** the execution states and states of the transition system **coincide** because the execution mechanism is simple.
- For more complex forms of plans (defined in later lectures when discussing planning without full observability) the execution states also include information that encodes **memory** from earlier states of execution.

Summary

Plan objectives

Bounded reachability

- The simplest objective for nondeterministic planning is the one we have used in last lectures: reach a goal state with certainty.
- With this objective the nondeterminism can also be understood as **an opponent** like in 2-player games or in n -player games in general.
Plan guarantees reaching a goal state no matter what the opponent does: plans are **winning strategies**.

Plan objectives

Bounded reachability

AI Planning

Definition

Let $\langle S, I, O, G, P \rangle$ be a transition system with full observability and $\pi : S \rightarrow O$ a mapping from states to operators.

Then π is a plan for **bounded reachability** if

all maximal paths starting from an initial node have a finite length and end in a goal node.

This rules out infinite paths.

Bounded reachability

Looping

Maintenance

Summary

Need for unbounded executions / looping

- The first planning algorithm finds plans that reach a goal state without visiting any state twice.
- This property guarantees that the length of executions is bounded by some constant (which is smaller than the number of states.)
- Some solvable problems are not solvable this way.
 - ① Action may fail to have any effect.
Hit a coconut to break it.
 - ② Action may fail and take us away from the goals.
Build a house of cards.

Consequences:

- ① It is impossible to avoid visiting some states several times.
- ② There is no finite upper bound on execution length.

AI Planning

Exec. graphs

Looping

Algorithm idea

Subprocedure *prune*

Algorithm

Maintenance

Summary

Need for plans with unbounded executions

AI Planning

Assumption

- 1 For any nondeterministic effect $e_1 | \dots | e_n$ the probability of every effect e_1, \dots, e_n is > 0 .
- 2 For any $s' \in \text{img}_o(s)$ the probability of reaching s' from s by o is > 0 .

This assumption guarantees that any path in the execution graph has a non-zero probability.

This is **not compatible** with viewing nondeterminism as an opponent in a 2-player game: the opponent's strategy might rule out some of the choices e_1, \dots, e_n .

Plan objectives

Unbounded reachability

Definition

Let $\langle S, I, O, G, P \rangle$ be a transition system with full observability and $\pi : S \rightarrow O$ a mapping from states to operators.

Then π is a plan for **unbounded reachability** if

from every node to which there is a path from an initial node there is a path to a goal node that is a terminal node.

Looping

These plans may **loop** i.e. visit and revisit a state an unbounded number of times.

These plans even allow **infinite executions that do not reach a goal state** but the probability of such executions under the assumption we made is 0.

Summary

Algorithm for unbounded reachability

- We give an algorithm that finds plans that may loop (unbounded reachability.)
- The algorithm is rather tricky in comparison to the algorithm for bounded reachability.
- Every state covered by a plan satisfies two properties:
 - 1 The state is **good**: there is at least one execution (= path in the execution graph) leading to a goal state.
 - 2 Every successor state is either a goal state or good.
- The algorithm repeatedly eliminates states that are not good.

Algorithm idea

Subprocedure *prune*

Algorithm

Maintenance

Summary

Subprocedure *prune*

- The procedure **prune** finds a maximal set of states for which reaching goals with looping is possible.
- Two nested loops.
 - 1 Inner loop identifies sets S_j of states from which a goal state can be reached with j steps without leaving the current set of candidate good states W_i .
Limit of S_0, S_1, \dots will be W_{i+1} .
 - 2 Outer loop iterates through $i = 0, 1, 2, \dots$ and produces a decreasing sequence of candidate good state sets W_0, W_1, \dots, W_n until $W_n = W_{n+1}$.

13:    $\pi(s) := o$  such that  $\text{img}_o(s) \subseteq L$  and  $\text{img}_o(s) \cap D_{d-1} \neq \emptyset$ ;
14: END DO
```

AI Planning

Exec. graphs

Looping

Algorithm idea

Subprocedure *prune*

Algorithm

Maintenance

Summary

Complexity of the planning algorithm

- The procedure *prune* runs in polynomial time in the number of states because the number of iterations of each loop is at most n – hence there are $O(n^2)$ iterations – and computation on each iteration takes polynomial time in the number of states.
- Finding conditional plans for full observability under the bounded and unbounded reachability objectives is in the complexity class EXPTIME.
- Lecture notes contain proofs showing that the planning problems are also EXPTIME-hard.

AI Planning

Exec. graphs

Looping

Algorithm idea

Subprocedure *prune*

Algorithm

Maintenance

Summary

Maintenance goals

- Planning is often not about reaching a goal state in which execution can be terminated.
 - ① An animal: find food, eat, sleep, find food, eat, sleep, ...
 - ② Cleaner robot: keep the building clean.
- These problems cannot be directly formalized in terms of reachability because infinite (unbounded) plan execution is needed.
- We next formalize the simplest objective with infinite plan executions which is known as **maintenance** because the transition system has to be kept in the goal states indefinitely (the condition expressed by the goals has to be *maintained*.)

Plan objectives

Maintenance

AI Planning

Exec. graphs

Looping

Maintenance

Definition

Example

Algorithm

Summary

Definition

Let $\langle S, I, O, G, P \rangle$ be a transition system with full observability and $\pi : S \rightarrow O$ a mapping from states to operators.

Then π is a plan for **maintenance** if

every node in the execution graph to which there is a path from an initial node is a goal node that has a successor node.

The execution graph does not have terminal nodes.

Maintenance

Example

- The state of an animal is determined by three state variables: hunger (0,1,2), thirst (0,1,2) and location (river, pasture, desert). There is also a special state called **death**.
- Thirst grows when not at river; at river it is 0.
- Hunger grows when not on pasture; on pasture it is 0.
- If hunger or thirst exceeds 2, the animal dies.
- The goal of the animal is to not die.

Looping

Maintenance

Definition

Example

Algorithm

Summary

Maintenance goals

Example

We can infer rules backwards starting from the death condition.

- 1 If in desert and **thirst = 2** must go to river.
- 2 If in desert and **hunger = 2** must go to pasture.
- 3 If on pasture and **thirst = 1** must go to desert.
- 4 If at river and **hunger = 1** must go to desert.
- 5 ...

If the above rules conflict, the animal will die.

There is only one plan: go to pasture, go to desert, go to river, go to desert, ...

AI Planning

Exec. graphs

Looping

Maintenance

Definition

Example

Algorithm

Summary

Algorithm for maintenance goals

Idea

- 1 Goal states are **0-safe**: maintenance objective is satisfied for the current state.
- 2 Given all i -safe states, compute all **$i + 1$ -safe** states: maintenance objective is satisfied for $i + 1$ time points.
- 3 $i + 1$ -safe states can be computed from i -safe states by using strong preimages.
- 4 For some j , j -safe states equal $j + 1$ -safe states because there are only finitely many states and at each step $j + 1$ -safe states are a subset of j -safe states. Then j -safe states are also ∞ -safe.

Summary of the algorithm idea

Repeatedly eliminate from consideration those states that in 1 or more steps unavoidably lead to a non-goal state.

AI Planning

Exec. graphs

Looping

Maintenance

Summary

Summary

- There are several possible objectives a plan can fulfill.
- We have considered **bounded reachability**, **unbounded reachability** and **maintenance**.
The executions are respectively of bounded finite length, unbounded finite length, and infinite.
- These objectives have all been formalized in terms of the properties of **execution graphs**.
- We have presented dynamic-programming type (backward search) algorithms for all three planning problems.
- All three algorithms can be implemented by using binary decision diagrams BDDs as a data structure for state sets.
