Combinatorial Auctions

Single-Minded Bidders

Summary

Combinatorial Auctions

Combinatorial Auctions

Motivation:

- Multiple items are auctioned concurrently.
- Bidders have preferences for combinations (bundles) of items.
- Items can complement or substitute one another.
 - **complement:** left and right shoe together.
 - substitute: two right shoes.
- Aim: socially optimal allocation of items to bidders.

Combinatorial Auctions

> Single-Minded Bidders

Combinatorial Auctions

Applications:

- Spectrum auctions (with combinations of spectrum bands and geographical areas)
- Procurement of transportation services for multiple routes

...

Notation:

- Items: *G* = {1,...,*m*}
- Bidders: *N* = {1,...,*n*}

Combinatorial Auctions

DRG

2

Single-Minded Bidders

Combinatorial Auctions

Definition (valuation)

A valuation is a function $v : 2^G \to \mathbb{R}^+$ with $v(\emptyset) = 0$ and $v(S) \le v(T)$ for $S \subseteq T \subseteq G$.

- Requirement $v(\emptyset) = 0$ to "normalize" valuations.
- Requirement $v(S) \le v(T)$ for $S \subseteq T \subseteq G$: monotonicity (or "free disposal").
- Let $S, T \subseteq G$ be disjoint.
 - *S* and *T* are complements to each other if $v(S \cup T) > v(S) + v(T)$.
 - *S* and *T* are substitutes if $v(S \cup T) < v(S) + v(T)$.

Combinatorial Auctions

2

Single-Minded Bidders

Allocations

UNI FREIBURG

Definition (allocation)

An allocation of the items to the bidders is a tuple $\langle S_1, \ldots, S_n \rangle$ with $S_i \subseteq G$ for $i = 1, \ldots, n$ and $S_i \cap S_j = \emptyset$ for $i \neq j$.

The social welfare obtained by an allocation is $\sum_{i=1}^{n} v_i(S_i)$ if v_1, \ldots, v_n are the valuations of the bidders.

An allocation is called socially efficient if it maximizes social welfare among all allocations.

Let A be the set of all allocations.

Combinatorial Auctions

Single-Minded Bidders

Winner Determination Problem

Definition (winner determination problem)

Let $v_i : 2^G \to \mathbb{R}^+$, i = 1, ..., n, be the declared valuations of the bidders. The winner determination problem (WDP) is the problem of finding a socially efficient allocation $a \in A$ for these valuations.

Aim: Develop mechanism for WDP.

Challenges:

- Incentive compatibility
- Complexity of representation and communication of preferences (exponentially many subsets of items!)
- Computational complexity

Combinatorial Auctions

Combinatorial Auctions

Single-Minded Bidders

Definitions

Complexity

Greedy Mechanism for Single-Minded Bidders

Properties of Greedy Mechanism

Summary

Single-Minded Bidders

Special Case: Single-Minded Bidders

Motivation:

- Focus on single-minded bidders: cuts complexity of representation down to polynomial space.
- Idea: single-minded bidder focuses on one bundle, has fixed valuation v* for that bundle (and its supersets), valuation 0 for all other bundles.

Comb

> torial Auctions

Single-Minded Bidders

Definitions

Complexity

Greedy Mechanism for Single-Minded Bidders

Properties of Greedy Mechanism

Single-Minded Bidders

Definition (single-minded bidder)

A valuation v is called single-minded if there is a bundle $S^* \subseteq G$ and a value $v^* \in \mathbb{R}^+$ such that

$$v(S) = \begin{cases} v^* & \text{if } S^* \subseteq S \\ 0 & \text{otherwise} \end{cases}$$

A single-minded bid is a pair $\langle S^*, v^* \rangle$.

Representational complexity: solved.

Computational complexity: not solved.

Greedy Mechanism for Single-Minded

Bidders Properties of Greedy Mechanism

Allocation Problem for Single-Minded Bidders

Definition (allocation problem for single-minded bidders)

The allocation problem for single-minded bidders (APSMB) is defined by the following input and output.

INPUT. Bids
$$\langle S_i^*, v_i^* \rangle$$
 for $i = 1, ..., n$

■ OUTPUT. $W \subseteq \{1, ..., n\}$ with $S_i^* \cap S_j^* = \emptyset$ for $i, j \in W$, $i \neq j$ such that $\sum_{i \in W} v_i^*$ is maximized.

Claim: APSMB is NP-complete.

Properties of Greedy Mechanism

Allocation Problem for Single-Minded Bidders

Since APSMB is an optimization problem, consider the corresponding decision problem:

Definition (allocation problem for single-minded bidders, decision problem)

The decision problem version of APSMB (APSMB-D) is defined by the following input and output.

- **INPUT.** Bids $\langle S_i^*, v_i^* \rangle$ for i = 1, ..., n and $k \in \mathbb{N}$
- **OUTPUT.** Is there a $W \subseteq \{1, ..., n\}$ with $S_i^* \cap S_j^* = \emptyset$ for $i, j \in W, i \neq j$ such that $\sum_{i \in W} v_i^* \geq k$?

Theorem

APSMB-D is NP-complete.

UNI FREIBURG

Combina torial Auctions

Single-Minded Bidders

Definitions

Complexity

Greedy Mechanism for Single-Minded Bidders

Properties of Greedy Mechanism

Proof (ctd.)

Since $S_i^* \cap S_j^* = \emptyset$ for $i, j \in W$, $i \neq j$, the set of winners W represents an independent set of cardinality

$$|W| = \sum_{i \in W} v_i^*.$$

Therefore, there is an independent set of cardinality at least k_{lS} iff there is a set of winners W with $\sum_{i \in W} v_i^* \ge k$. This proves NP-hardness.

APSMB-D \in NP: obvious (guess and verify set of winners).

 - heuristic approach
 - special cases
- Here: approximation algorithm

Combinatorial Auctions

Single-Minded Bidders

Definitions

Complexity

Greedy Mechanism for Single-Minded Bidders

Properties of Greedy Mechanism

Approximation Algorithms

Definition (approximation factor)

Let $c \ge 1$. An allocation $\langle S_1, \dots, S_n \rangle$ is a *c*-approximation of an optimal allocation if

$$\sum_{i=1}^n v_i(T_i) \le c \cdot \sum_{i=1}^n v_i(S_i)$$

for an optimal allocation $\langle T_1, \ldots, T_n \rangle$.

Proposition

Approximating APSMB within a factor of $c \le m^{1/2-\varepsilon}$ for any $\varepsilon > 0$ is NP-hard.

Definitions

Complexity

Greedy Mechanism for Single-Minded Bidders

Properties of Greedy Mechanism

Approximation Algorithms

Best we can still hope for in case of single-minded bidders:

- incentive compatible
- **m**^{1/2}-approximation algorithm</sup>
- with polynomial runtime.

Good news:

Such an algorithm exists!

Combinatorial Auctions

Single-Minded Bidders

Definitions

Complexity

Greedy Mechanism for Single-Minded Bidders

Properties of Greedy Mechanism

Definition (mechanism for single-minded bidders)

Let V_{sm} be the set of all single-minded bids and A the set of all allocations.

A mechanism for single-minded bidders is a tuple $\langle f, p_1, \dots, p_n \rangle$ consisting of

- a social choice function $f: V_{sm}^n \to A$ and
- **payment functions** $p_i : V_{sm}^n \to \mathbb{R}$ for all i = 1, ..., n.

Combinatorial Auctions

> Single-Minded Bidders

Definitions

Greedy Mechanism for Single-Minded Bidders

Properties of Greedy Mechanism

Definition (efficient computability)

A mechanism for single-minded bidders is efficiently computable if f and all p_i can be computed in polynomial time.

Definition (incentive compatibility)

A mechanism for single-minded bidders is incentive compatible if

$$v_i(f(v_i, v_{-i})) - p_i(v_i, v_{-i}) \ge v_i(f(v'_i, v_{-i})) - p_i(v'_i, v_{-i})$$

for all i = 1, ..., n and all $v_1, ..., v_n, v'_i \in V_{sm}$, where $v_i(a) = v^*_i$ if i wins in a (gets the desired bundle), and $v_i(a) = 0$, otherwise.

Combinatorial Auctions

Single-Minded Bidders

Definitions

Complexity

Greedy Mechanism for Single-Minded Bidders

Properties of Greedy Mechanism

How to build such a mechanism?

- In principle: could use a VCG mechanism.
- Problem with VCG: incentive compatible, but not efficiently computable

(need to compute social welfare, which is NP-hard)

- Alternative idea: VCG-like mechanism that approximates social welfare
- Problem with alternative: efficiently computable, but not incentive compatible
- Solution: forget VCG, use specific mechanism for single-minded bidders.

Properties of Greedy Mechanism

Proof (ctd.)

■ (B.2.a) Lying about desired bundle does not help. Show that $\langle S^*, v' \rangle$ is at least as good as $\langle S', v' \rangle$.

Let p' be the payment for bid $\langle S', v' \rangle$ and p the payment for bid $\langle S^*, v' \rangle$.

For all x < p, $\langle S^*, x \rangle$ is losing, since p is the critical payment for S^* .

Due to monotonicity, also $\langle S', x \rangle$ is losing for all x < p. Hence, the critical payment p' for S' is at least p.

Thus, $\langle S^*, v' \rangle$ is still winning, if $\langle S', v' \rangle$ was, and leads to the same or even lower payment.

Corollary

The greedy mechanism for single-minded bidders is incentive compatible.

Open question:

• What about approximation factor of \sqrt{m} ?

In the next proof, we will need the Cauchy-Schwarz inequality:

Theorem (Cauchy-Schwarz inequality)

Let $x_j, y_j \in \mathbb{R}$. Then

$$\sum_{j} x_{j} y_{j} \leq \sqrt{\sum_{j} x_{j}^{2}} \cdot \sqrt{\sum_{j} y_{j}^{2}}$$

Single-Minded Bidders

Summary

Summary

B. Nebel, R. Mattmüller – Game Theory

- In combinatorial auctions, bidders bid for bundles of items.
- Exponential space needed just to represent and communicate valuations.
- Therefore: Focus on special case of single-minded bidders (compact representation of valuations).
- Unfortunately, still, optimal allocation NP-hard.
- Solution: approximate optimal allocation.
- Polynomial-time approximation possible for approximation factor no better than \sqrt{m} .
- Greedy mechanism for single-minded bidders:
 - achieves \sqrt{m} -approximation of social welfare,
 - is efficiently computable, and
 - **is** incentive compatible.
