Motivation for studying modal logics

- Notions like **believing** and **knowing** require a more general semantics than e.g. propositional logic has.
- Some KR formalisms can be understood as (fragments of) a **propositional modal logic**.
- Application 1: Spatial representation formalism **RCC8**
- Application 2: **Description logics**
- Application 3: Reasoning about time
- Application 4: Reasoning about actions, strategies, etc.

Motivation

Syntax

Semantics

Different
Logics

Analytic
Tableaux

Outlook &
literature

Motivation for modal logics

Often, we want to state something where we have an “**embedded proposition**”:

- John believes that **it is Sunday**.
- I know that $2^{10} = 1024$.

Reasoning with embedded propositions:

- *John believes that if it is Sunday, then shops are closed.*
- *John believes that it is Sunday.*
- This implies (assuming **belief** is closed under **modus ponens**):
John believes that shops are closed.

Semantics: the idea

In classical propositional logic, formulae are interpreted over single interpretations and are evaluated to **true** or **false**.

In modal logics one considers **sets** of interpretations: **possible worlds** (physically possible, conceivable, ...).

Validity: some examples

Theorem

K is **K**-valid.

$$K = \Box(\varphi \rightarrow \psi) \rightarrow (\Box\varphi \rightarrow \Box\psi)$$

Proof.

Let \mathcal{I} be an interpretation and let w be a world in \mathcal{I} .

Assume $\mathcal{I}, w \models \Box(\varphi \rightarrow \psi)$, i.e., in all worlds u with wRu , if φ is true then also ψ is. (Otherwise K is true in w anyway.)

If $\Box\varphi$ is false in w , then $(\Box\varphi \rightarrow \Box\psi)$ is true and K is true in w .

If $\Box\varphi$ is true in w , then both $\Box(\varphi \rightarrow \psi)$ and $\Box\varphi$ are true in w .

Tableau rules for other modal logics

Proofs within more restricted classes of frames allow the use of further tableau rules.

- For reflexive (**T**) frames we may extend any branch with wRw .
- For transitive (**4**) frames we have the following additional rule:
 - If wRv and vRu are in a branch, wRu may be added to the branch.
- For serial (**D**) frames we have the following rule:
 - If there is $w \models \dots$ or $w \not\models \dots$ on a branch, then add wRv for a new world v .
- Similar rules for other properties...

Complexity of simple modal logics

How hard is it to check whether a modal logic formula is satisfiable or valid?

The answer depends in fact on the **considered class of frames!**

For example, one can show that each formula φ that is satisfiable in some S5-frame is satisfiable in an S5-frame with

$$|W| \leq |\varphi|.$$

Proposition

Checking whether a modal formula is satisfiable in some S5-model is NP-complete (and hence checking S5-validity is coNP-complete).

For other modal logics, such as K, KT, KD, K4, S4, these problems are PSPACE-complete.

Connection between propositional modal logic and FOL?

Motivation

Syntax

Semantics

Different Logics

Analytic Tableaux

Embedding in FOL

Outlook & literature

- There are similarities between predicate logic and propositional modal logics:

1 \Box vs. \forall

2 \Diamond vs. \exists

3 possible worlds vs. objects of the universe

- In fact, many propositional modal logics can be embedded in the predicate logic.

⇒ Modal logics can be understood as a sublanguage of FOL.

Embedding modal logics into FOL (1)

1 $\tau(p, x) = p(x)$ for propositional variables p

Embedding modal logics into FOL (2)

Theorem

φ is K-valid if and only if $\forall x \tau(\varphi, x)$ is valid in FOL.

Theorem

φ is T-valid if and only if in FOL the logical consequence $\{\forall x R(x, x)\} \models \forall x \tau(\varphi, x)$ holds.

Example

$\Box p \wedge \Diamond(p \rightarrow q) \rightarrow \Diamond q$ is K-valid, because

$$\forall x (\forall x' (R(x, x') \rightarrow p(x')) \wedge \exists x' (R(x, x') \wedge (p(x') \rightarrow q(x')))) \\ \rightarrow \exists x' (R(x, x') \wedge q(x'))$$

is valid in FOL.
