

Principles of Knowledge Representation and Reasoning

Reasoning about Actual Causality

Bernhard Nebel, Felix Lindner, and Thorsten Engesser

April 17, 2018

Motivation

- AI systems are used or are about to be used in many domains that potentially affect people's life significantly: Finance, Law, Health etc.
- According to The European Union General Data Protection Regulation, everyone has the right to obtain an explanation of the decision reached [...] and to challenge the decision.
- In AI, there is currently a huge interest in so-called Explainable AI (XAI), i.e., the design and analysis of systems that are able to explain their decisions to humans.
- That's a perfect reason (among others) to study causal reasoning as a means to come up with answers to Why-questions, i.e., explanations.

Causal
Models

Literature

Causation

Pearl's
Ladder of
Causation

Causal
Models

Literature

- Everyone who has ever taken a statistics class has probably been told that correlation is not causation. But what is causation then?
- We will first learn about Judea Pearl's Ladder of Causation distinguishing three reasoning modes: Association (Seeing), Intervention (Doing), and Introspection (Imagining).
- We will then study Judea Pearl's and Joseph Halpern's attempts to define causality and related concepts based on causal models [1, 2].

Association: Seeing

Pearl's
Ladder of
Causation

Causal
Models

Literature

- Answers questions like “What if I see ...”?, “How would seeing X change my belief in Y?”
- E.g.: Seeing a high number on the thermometer makes me believe it is sunny outside. Seeing features X, Y, Z in an image makes the AI believe that there is a cat on the picture.
- Correlation between variables.

Intervention: Doing

Pearl's
Ladder of
Causation

Causal
Models

Literature

- Answers questions like “What if I do . . .”, “What would Y be if I do X?”, “How can I make Y happen?”
- E.g.: Taking an aspirin will cure my headache. But, heating the thermometer will not make the sun shine.
- This type of reasoning requires to disentangle otherwise correlated variables.

Introspection: Imagining

- Answers questions like “What if I had (not) done . . . ?”, “Was it X that caused Y?”, “What if X had not occurred?”
- Being able to answer such question is a prerequisite for AI systems to reason about:
 - Regret: Would things have turned out better if I had acted otherwise?
 - Responsibility: To what extend was it my action that caused X?
 - Blame: Could/Should I have known that my action will cause X?
- This type of reasoning requires to fix some variables to the value they had in a particular situation while changing the values of other variables, i.e., considering counterfactual worlds.

Causation

Causal
Models

Literature

2 Causal Models

Pearl's
Ladder of
Causation

**Causal
Models**

Literature

Definition: Causal Model

Definition (Causal Model)

A **causal model** M is a pair $(\mathcal{S}, \mathcal{F})$, where

- $\mathcal{S} = (\mathcal{U}, \mathcal{V}, \mathcal{R})$ is a signature, which explicitly lists the **exogeneous variables** \mathcal{U} , the **endogeneous variables** \mathcal{V} , and associates with every variable $Y \in \mathcal{U} \cup \mathcal{V}$ a non-empty set $\mathcal{R}(Y)$ of possible values for Y ,
- \mathcal{F} associates one **structural equation** F_X to each endogeneous variable $X \in \mathcal{V}$:

$$F_X : \mathcal{R}(Z_1) \times \dots \times \mathcal{R}(Z_{|\mathcal{U} \cup \mathcal{V}|-1}) \rightarrow \mathcal{R}(X) \text{ for all } Z_i \in \mathcal{U} \cup \mathcal{V} - \{X\}$$

Terminology

Pearl's
Ladder of
Causation

Causal
Models

Literature

- **Model M** : Specification of the available variables (exogeneous and endogeneous) and their structural relationships (via structural equations).
- **Context \vec{u}** : An assignment of values to the exogeneous variables. (From this assignment, the values of the endogeneous variables can be deterministically determined).
- **Situation (M, \vec{u})** : A pair of a model and a context determines a situation. In a situation, every variable in the model has got a value.

Definition (Intervention)

An **intervention** sets the value of some endogeneous variable X to a value x in a causal model $M = (\mathcal{S}, \mathcal{F})$ resulting in a new causal model $M_{X \leftarrow x} = (\mathcal{S}, \mathcal{F}_{X \leftarrow x})$, where $\mathcal{F}_{X \leftarrow x}$ results from replacing the structural equation for X in \mathcal{F} by $X = x$ and leaving the remaining equations untouched.

- Interventions enable counterfactual reasoning by setting values different from actual values thereby overriding structural equations.

Independence and Recursiveness I

Pearl's
Ladder of
Causation

Causal
Models

Literature

Definition (Independence)

Endogenous variable Y is independent of endogenous variable X in a setting (M, \vec{u}) iff for all settings \vec{z} of the endogenous variables other than X and Y , and all values x, x' of X , $F_Y(x, \vec{z}, \vec{u}) = F_Y(x', \vec{z}, \vec{u})$ holds.

Definition (Recursive Model)

A model M is **recursive** iff for each context \vec{u} , there is a partial order $\preceq_{\vec{u}}$ (reflexive, anti-symmetric, transitive) of the endogenous variables, such that unless $X \preceq_{\vec{u}} Y$, Y is independent of X in (M, \vec{u}) .

Independence and Recursiveness II

- Independence may vary depending on context \vec{u} . Consider $M = (\mathcal{S}, \mathcal{F})$:
 - $\mathcal{S} = (\{C\}, \{X, Y\}, \{C \mapsto \{0, 1\}, X \mapsto \{0, 1\}, Y \mapsto \{0, 1\}\})$
 - $\mathcal{F} = \{X := (C = 1) \wedge (Y = 1), Y := (C = 1) \vee (X = 1)\}^1$
- Case $\vec{u} = (0)$: X is independent of Y , Y depends on X .
- Case $\vec{u} = (1)$: X depends on Y , Y is independent of X .

¹We here abuse notation a bit.

Independence and Recursiveness III

Pearl's
Ladder of
Causation

Causal
Models

Literature

- For a recursive model M and context \vec{u} , the value of all endogenous variables can be determined deterministically:
 - First, determine values of variables that depend only on \vec{u} (first level).
 - Second, determine values of variables that depend only on \vec{u} and first-level variables (second level).
 - ...
- In everything that follows, “causal model” will always mean “recursive causal model”.

Language of Causality: Syntax

Pearl's
Ladder of
Causation

Causal
Models

Literature

- Given a signature $\mathcal{S} = (\mathcal{U}, \mathcal{V}, \mathcal{R})$. A causal formula over \mathcal{S} is one of the form $[Y_1 \leftarrow y_1, \dots, Y_k \leftarrow y_k]\varphi$, where
 - φ is a boolean combination (using $\wedge, \vee, \neg, \rightarrow$) of primitive events (of the form $X = x$), and
 - Y_1, \dots, Y_k are distinct variables in \mathcal{V} , and
 - $y_i \in \mathcal{R}(Y_i)$.
- Common abbreviation: $[\vec{Y} \leftarrow \vec{y}]\varphi$
- Case $k = 0$: $[\]\varphi$ is also just written as φ

Language of Causality: Semantics

Pearl's
Ladder of
Causation

Causal
Models

Literature

- Truth of a causal formula is validated relative to a causal model M and a context \vec{u} .
- $(M, \vec{u}) \models X = x$ iff the value of X is x once the exogeneous variables are set to \vec{u} .
- $(M, \vec{u}) \models [\vec{Y} \leftarrow \vec{y}] \varphi$ iff $(M_{\vec{Y} \leftarrow \vec{y}}, \vec{u}) \models \varphi$
- Boolean combinations validated as usual: $(M, \vec{u}) \models \varphi \wedge \psi$ iff $(M, \vec{u}) \models \varphi$ and $(M, \vec{u}) \models \psi$ etc.

Definition (Cause according to Hume)

“We may define a cause to be an object followed by another, and where all the objects, similar to the first, are followed by objects similar to the second. Or, in other words, where, if the first object had not been, the second never had existed.”

Definition (But-For Cause)

$X = x$ is a **but-for cause** of φ in (M, \vec{u}) iff

- $(M, \vec{u}) \models (X = x) \wedge \varphi$, and
- there exists some x' , s.th. $(M, \vec{u}) \models [X \leftarrow x'] \neg \varphi$

Forest Fire: Conjunctive

Example (Conjunctive Forest Fire)

- Consider M^c with exogeneous variable U , and endogeneous variables L (lightning), MD (dropped match), FF (forest fire), s.th. $\mathcal{R}(U) = \{(0,0), (0,1), (1,0), (1,1)\}$, $\mathcal{R}(L) = \mathcal{R}(MD) = \mathcal{R}(FF) = \{0,1\}$, and $L := U = (1,0) \vee U = (1,1)$, $MD := U = (0,1) \vee U = (1,1)$, $FF := L = 1 \wedge MD = 1$.
- Did the lightning (L) cause the forest fire (FF) in situation $M, (1,1)$? Check for but-for cause:
 - $(M, (1,1)) \models L = 1 \wedge FF = 1$
 - $(M, (1,1)) \models [L \leftarrow 0] \neg FF$
- Answer: Yes.

Forest Fire: Disjunctive

Example (Disjunctive Forest Fire)

- Consider M^d , which differs from M^c only in the structural equation for FF , viz., $FF := L = 1 \vee MD = 1$.
- Again: Did the lightning (L) cause the forest fire (FF) in situation M , $(1, 1)$? Check for but-for cause:
 - $(M, (1, 1)) \models L = 1 \wedge FF = 1$
 - $(M, (1, 1)) \not\models [L \leftarrow 0] \neg FF$
- Answer: No.
- Using the same reasoning, MD also is not a cause according to the but-for definition of causality.
- (But $L \vee MD$ is.)
