

An Introduction to Game Theory Part III:

Strictly Competitive Games

Bernhard Nebel

Strictly Competitive Games

- A **strictly competitive** or **zero-sum** game is a 2-player strategic game such that for each $a \in A$, we have $u_1(a) + u_2(a) = 0$.
 - What is good for me, is bad for my opponent and *vice versa*
- Note:** Any game where the sum is a constant c can be transformed into a zero-sum game with the **same set of equilibria**:
 - $u'_1(a) = u_1(a)$
 - $u'_2(a) = u_2(a) - c$

How to Play Zero-Sum Games?

- Assume that only *pure strategies* are allowed
- **Dominating strategy?**
- **Nash equilibrium?**
- Be paranoid: Try to minimize your loss by assuming the worst!
- Player 1 takes **minimum** over row values:
 - T: -6, M: -1, B: -6
- then **maximizes**:
 - M: -1

	L	M	R
T	8,-8	3,-3	-6,6
M	2,-2	-1,1	3,-3
B	-6,6	4,-4	8,-8

Maximinimizer

- An action x^* is called **maximinimizer** for player 1, if

$$\min_{y \in A_2} u_1(x^*, y) \geq \min_{y \in A_2} u_1(x, y) \text{ for all } x \in A_1$$
- Similar for player 2
- Maximinimizer try to minimize the loss, but do not necessarily lead to a Nash equilibrium.
- However, if a NE exists, then the action profile is a pair of maximinimizers!

Maximinimizer Theorem

In strictly competitive games:

- If (x^*, y^*) is a Nash equilibrium of G then x^* is a maximinimizer for player 1 and y^* is a maximinimizer for player 2.
- If (x^*, y^*) is a Nash equilibrium of G then $\max_x \min_y u_1(x, y) = \min_y \max_x u_1(x, y) = u_1(x^*, y^*)$.
- If $\max_x \min_y u_1(x, y) = \min_y \max_x u_1(x, y)$ and x^* is a maximinimizer for player 1 and y^* is a maximinimizer for player 2, then (x^*, y^*) is a Nash equilibrium.

Some Consequences

- Because of (2): if (x^*, y^*) is a NE then $\max_x \min_y u_1(x, y) = u_1(x^*, y^*)$, all NE yield the **same payoff**
 - it is irrelevant which we choose.
- Because of (2), if (x^*, y^*) and (x', y') are NEs then x^*, x' are maximinimizers for player 1 and y^*, y' are maximinimizers for player 2. Because of (3), then (x^*, y') and (x', y^*) are NEs as well!
 - it is not necessary to coordinate in order to play in a NE!

Example

- Minimum in rows (for player 1):
 - T: -6, M: -1, B: -6
- Maximinimizer:
 - M: -1
- Maximum over columns (for player 1)
 - L: 8, M: -1, R: 8
- Minimaximizer:
 - M: -1
- Also NE, apparently

	L	M	R
T	8,-8	-3,3	-6,6
M	2,-2	-1,1	3,-3
B	-6,6	-4,4	8,-8

How to Find NEs in Mixed Strategies?

- While it is **non-trivial** to find NEs for **general sum** games, **zero-sum** games are **"easy"**
- Let's test all mixed strategies of player 1 α_1 against all mixed strategies of player 2 α_2 . Then use only those that are **maximinimizers**.
- Since all mixed strategies are linear combinations of pure strategies, it is enough to check against the **pure strategies** of player 2 (support theorem).
- We just have to **optimize**, i.e., find the best mixed strategy
 - Use **linear programming**

Linear Programming: The Idea

- The **article-mix** problem:
 - **article 1** needs: 25 min of cutting, 60 min of assembly, 68 min of postprocessing
 - results in **30 Euro profit** per article
 - **article 2** needs: 75 min of cutting, 60 min of assembly, and 34 min of postprocessing
 - results in **40 Euro profit** per article
 - **per day**: 450 min of cutting, 480 min of assembly and 476 min of postprocessing
- Try to maximize profit

Resulting Constraints & Optimization Goals

- x : #article1, y : #article2
- $x \geq 0, y \geq 0$
- $25x + 75y \leq 450$ (cutting)
 - $y \leq 6 - (1/3 \cdot x)$
- $60x + 60y \leq 480$ (assembly)
 - $y \leq 8 - x$
- $68x + 34y \leq 476$ (postprocessing)
 - $y \leq 14 - 2x$
- **Maximize** $z = 30x + 40y$

Feasible Solutions

- The inequalities describe **convex sets** in \mathbb{R}^2
- The intersection of all convex sets represents the set of **feasible solutions**
- Each point in the set of feasible solutions could get a **quality measure** according to the objective function
- Consider lines of equal quality and then do hill climbing!

Linear Programming: The General Case

- n real-valued **variables** x_i
- m **coefficients** b_j and **constants** c_j
- $m \cdot n$ coefficients a_{ij}
- m **equations** $\sum_i a_{ij} x_i = c_j$
- **objective function**: $\sum_i b_i x_i$ is to be minimized
- Can be solved by the **simplex method**
 - **lpsolve** (under Linux)

Solving Zero-Sum Games

- Let $A_1 = \{a_{11}, \dots, a_{1n}\}$, $A_2 = \{a_{21}, \dots, a_{2m}\}$,
- Player 1 looks for a mixed strategy α_1
 - $\sum_j \alpha_1(a_{1j}) = 1$
 - $\alpha_1(a_{1j}) \geq 0$
 - $\sum_j \alpha_1(a_{1j}) \cdot u_1(a_{1j}, a_{2i}) \geq u$ for all $i \in \{1, \dots, m\}$
 - **Maximize u !**
- Similarly for player 2.

Conclusion

- **Zero-sum** games are particularly simple
- Playing a pure **maximizing** strategy minimizes loss (for pure strategies)
- If **NE exists**, it is a pair of **maximinizers**
- NEs can be freely “**mixed**”
- In mixed strategies, NEs always exists
- Can be determined by **linear programming**
