

Logik für Informatiker: PROLOG  
Part 4: Accumulators, Programming Methodology  
& Second Order Predicates

Andreas Karwath

&

Wolfram Burgard

(original slides by Peter Flach)

- In Prolog, variables cannot be changed (logical variables)
- *Accumulator passing*:  
a function obtains the current value of a variable as an argument and returns the new value in a different variable
- Input argument: *accumulator*
- Output argument: *result*
- One „conventional“ variable → two Prolog arguments called the accumulator pair
- Very commonly used, very efficient
- „Recursive versions“ of predicates often waste memory
- „Accumulator versions“ only need constant *stack space*

```
length ([], 0).  
length ([H|T], N) :-  
    length(T, M),  
    N is M + 1.
```

```

?-length([a,b,c],N)      length([H|T],N1):-length(T,M1),
                        N1 is M1+1
                        |
                        H->a, T->[b,c], N1->N

    reverse(T, [H|Y0], Y).
```

# Logic Programming Methodology

**Problem:** Given a number  $N$ , define a predicate `partition/4`, that divides a list of numbers into two lists, one smaller than  $N$  and the other one containing the rest.

- Write down declarative specification

```
% partition(L,N,Littles,Bigs) <- Littles contains numbers
%                               in L smaller than N,
%                               Bigs contains the rest
```

- Identify **recursion** and **'output'** arguments

- Write down skeleton

```
partition([],N,[],[]).
partition([Head|Tail],N,?Littles,?Bigs):-
    /* do something with Head */
    partition(Tail,N,Littles,Bigs).
```

## ▪ Complete bodies

```

partition([],N,[],[]).
partition([Head|Tail],N,?Littles,?Bigs):-
    Head < N,
    partition(Tail,N,Littles,Bigs),
    ?Littles = [Head|Littles],?Bigs = Bigs.
partition([Head|Tail],N,?Littles,?Bigs):-
    Head >= N,
    partition(Tail,N,Littles,Bigs),
    ?Littles = Littles,?Bigs = [Head|Bigs].

```

## ▪ Fill in ‘output’ arguments

```

partition([],N,[],[]).
partition([Head|Tail],N,[Head|Littles],Bigs):-
    Head < N,
    partition(Tail,N,Littles,Bigs).
partition([Head|Tail],N,Littles,[Head|Bigs]):-
    Head >= N,
    partition(Tail,N,Littles,Bigs).

```

- Write down declarative specification

```
% sort(L,S) <- S is a sorted permutation of list L
```

- Write down skeleton

```
sort([], []).  
sort([Head|Tail], ?Sorted) :-  
    /* do something with Head */  
    sort(Tail, Sorted).
```

- Complete body (auxiliary predicate needed)

```
sort([], []).  
sort([Head|Tail], WholeSorted) :-  
    sort(Tail, Sorted),  
    insert(Head, Sorted, WholeSorted).
```

- Write down declarative specification

```
% insert(X,In,Out) <- In is a sorted list, Out is In
%                               with X inserted in the proper place
```

- Write down skeleton

```
insert(X, [], ?Inserted) .
insert(X, [Head|Tail], ?Inserted) :-
    /* do something with Head */
    insert(X, Tail, Inserted) .
```

## ▪ Complete bodies

```

insert(X, [], ?Inserted) :- ?Inserted = [X].
insert(X, [Head|Tail], ?Inserted) :-
    X > Head,
    insert(X, Tail, Inserted),
    ?Inserted = [Head|Inserted].
insert(X, [Head|Tail], ?Inserted) :-
    X =< Head,
    ?Inserted = [X, Head|Tail].

```

## ▪ Fill in ‘output’ arguments

```

insert(X, [], [X]).
insert(X, [Head|Tail], [X, Head|Tail]) :-
    X =< Head.
insert(X, [Head|Tail], [Head|Inserted]) :-
    X > Head,
    insert(X, Tail, Inserted).

```

```
sort([], []).
sort([Head|Tail], WholeSorted) :-
    sort(Tail, Sorted),
    insert(Head, Sorted, WholeSorted).
```

```
insert(X, [], [X]).
insert(X, [Head|Tail], [X, Head|Tail]) :-
    X <= Head.
insert(X, [Head|Tail], [Head|Inserted]) :-
    X > Head,
    insert(X, Tail, Inserted).
```

# Second-Order Predicates

```

parent(john,peter).
parent(john,paul).
parent(john,mary).
parent(mick,davy).
parent(mick,dee).
parent(mick,dozy).

?-findall(C,parent(john,C),L).
L = [peter,paul,mary]

?-findall(C,parent(P,C),L).
L = [peter,paul,mary,davy,dee,dozy]

?-bagof(C,parent(P,C),L).

P = john
L = [peter,paul,mary];

P = mick
L = [davy,dee,dozy]

?-bagof(C,P^parent(P,C),L).
L = [peter,paul,mary,davy,dee,dozy]

```

```
parent(john,peter).  
parent(john,paul).  
parent(john,mary).  
parent(mick,davy).  
parent(mick,dee).  
parent(mick,dozy).
```

```
?-findall(P,parent(P,C),L).
```

```
L = [john, john, john, mick, mick, mick]
```

```
?-setof(P,C^parent(P,C),L).
```

```
L = [john, mick]
```

Adding/retracting clauses from the program:

```
assert/1
```

```
retract/1
```

Have to be declared as *dynamic* before.

Example:

```
assert(student_of(peter, maria)).
```

```
assert((likes(X, Y) :- student_of(X, Y))).
```

```
retract ((likes(X, Y) :- student_of(X, Y))).
```

Constructing/decomposing an atom:

**Atom =.. [Predicate,Arg1,...,ArgN] .**

Example:

**p(X,c) =.. [p,X,c] .**

**p(X,c) =.. [P|Args] .**

**A =.. [p,X,c] .**

- **constant (Term)** : succeeds when **Term** is a constant
- **var (Term)** : succeeds when **Term** is a variable
- **ground (Term)** : succeeds when **Term** has no variable (i.e. is a ground term)
- **arg (N, Term, Arg)** : succeeds when **Arg** is the **N**th argument of **Term**
- **functor (Term, F, N)** : succeeds when the **Term** starts with the functor **F** of arity **N**.

Proving a goal:

```
call/1
```

Example:

```
call(likes(X, Y)).
```

Searching for clauses with a given head:

```
clause/2
```

Examples:

```
clause(likes(X,Y), Body).
```
