Principles of AI Planning

13. Computational complexity of classical planning

Malte Helmert

Albert-Ludwigs-Universität Freiburg

January 30th, 2009
How hard is planning?

- We have seen that planning can be done in time polynomial in the size of the transition system.
- However, we have not seen algorithms which are polynomial in the input size (size of the task description).

What is the precise computational complexity of the planning problem?
Why computational complexity?

- understand the problem
- know what is not possible
- find interesting subproblems that are easier to solve
- distinguish essential features from syntactic sugar
  - Is STRIPS planning easier than general planning?
  - Is planning for FDR tasks harder than for propositional tasks?
A nondeterministic Turing machine (NTM) is a 6-tuple \( \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle \) with the following components:

- **input alphabet** \( \Sigma \) and **blank symbol** \( \square \not\in \Sigma \)
  - alphabets always nonempty and finite
  - tape alphabet \( \Sigma_{\square} = \Sigma \cup \{\square\} \)
- **finite set** \( Q \) of **internal states** with **initial state** \( q_0 \in Q \) and **accepting state** \( q_Y \in Q \)
  - nonterminal states \( Q' := Q \setminus \{q_Y\} \)
- **transition relation** \( \delta \subseteq (Q' \times \Sigma_{\square}) \times (Q \times \Sigma_{\square} \times \{-1, +1\}) \)
A deterministic Turing machine (DTM) is an NTM where the transition relation is functional, i.e., for all $\langle q, a \rangle \in Q' \times \Sigma$, there is exactly one triple $\langle q', a', \Delta \rangle$ with $\langle \langle q, a \rangle, \langle q', a', \Delta \rangle \rangle \in \delta$.

**Notation:** We write $\delta(q, a)$ for the unique triple $\langle q', a', \Delta \rangle$ such that $\langle \langle q, a \rangle, \langle q', a', \Delta \rangle \rangle \in \delta$. 
Turing machine configurations

Definition (Configuration)

Let \( M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle \) be an NTM.

A configuration of \( M \) is a triple \( \langle w, q, x \rangle \in \Sigma^* \times Q \times \Sigma^+ \).

- \( w \): tape contents before tape head
- \( q \): current state
- \( x \): tape contents after and including tape head
Turing machine transitions

**Definition (yields relation)**

Let \( M = \langle \Sigma, \Box, Q, q_0, q_Y, \delta \rangle \) be an NTM.

A configuration \( c \) of \( M \) **yields** a configuration \( c' \) of \( M \),
in symbols \( c \vdash c' \), as defined by the following rules,
where \( a, a', b \in \Sigma_\Box, \; w, x \in \Sigma^*_\Box, \; q, q' \in Q \) and
\( \langle \langle q, a \rangle, \langle q', a', \Delta \rangle \rangle \in \delta \):

\[
\begin{align*}
(w, q, ax) \vdash (wa', q', x) & \quad \text{if } \Delta = +1, |x| \geq 1 \\
(w, q, a) \vdash (wa', q', \Box) & \quad \text{if } \Delta = +1 \\
(wb, q, ax) \vdash (w, q', ba'x) & \quad \text{if } \Delta = -1 \\
(\epsilon, q, ax) \vdash (\epsilon, q', \Box a'x) & \quad \text{if } \Delta = -1
\end{align*}
\]
### Definition (accepting configuration, time)

Let $M = \langle \Sigma, \Box, Q, q_0, q_Y, \delta \rangle$ be an NTM, let $c = \langle w, q, x \rangle$ be a configuration of $M$, and let $n \in \mathbb{N}_0$.

- If $q = q_Y$, $M$ accepts $c$ in time $n$.
- If $q \neq q_Y$ and $M$ accepts some $c'$ with $c \vdash c'$ in time $n$, then $M$ accepts $c$ in time $n + 1$.

### Definition (accepting configuration, space)

Let $M = \langle \Sigma, \Box, Q, q_0, q_Y, \delta \rangle$ be an NTM, let $c = \langle w, q, x \rangle$ be a configuration of $M$, and let $n \in \mathbb{N}_0$.

- If $q = q_Y$ and $|w| + |x| \leq n$, $M$ accepts $c$ in space $n$.
- If $q \neq q_Y$ and $M$ accepts some $c'$ with $c \vdash c'$ in space $n$, then $M$ accepts $c$ in space $n$. 
Accepting words and languages

**Definition (accepting words)**

Let $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$ be an NTM.

$M$ accepts the word $w \in \Sigma^*$ in time (space) $n \in \mathbb{N}_0$ iff $M$ accepts $(\epsilon, q_0, w)$ in time (space) $n$.

- Special case: $M$ accepts $\epsilon$ in time (space) $n \in \mathbb{N}_0$ iff $M$ accepts $(\epsilon, q_0, \square)$ in time (space) $n$.

**Definition (accepting languages)**

Let $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$ be an NTM, and let $f : \mathbb{N}_0 \rightarrow \mathbb{N}_0$.

$M$ accepts the language $L \subseteq \Sigma^*$ in time (space) $f$ iff $M$ accepts each word $w \in L$ in time (space) $f(|w|)$, and $M$ does not accept any word $w \notin L$ (in any time/space).
Definition (DTIME, NTIME, DSPACE, NSPACE)

Let $f : \mathbb{N}_0 \rightarrow \mathbb{N}_0$.

- Complexity class $\text{DTIME}(f)$ contains all languages accepted in time $f$ by some DTM.
- Complexity class $\text{NTIME}(f)$ contains all languages accepted in time $f$ by some NTM.
- Complexity class $\text{DSPACE}(f)$ contains all languages accepted in space $f$ by some DTM.
- Complexity class $\text{NSPACE}(f)$ contains all languages accepted in space $f$ by some NTM.
Let $\mathcal{P}$ be the set of polynomials $p : \mathbb{N}_0 \rightarrow \mathbb{N}_0$ whose coefficients are natural numbers.

**Definition (P, NP, PSPACE, NPSPACE)**

\[
\begin{align*}
\mathsf{P} &= \bigcup_{p \in \mathcal{P}} \text{DTIME}(p) \\
\mathsf{NP} &= \bigcup_{p \in \mathcal{P}} \text{NTIME}(p) \\
\mathsf{PSPACE} &= \bigcup_{p \in \mathcal{P}} \text{DSPACE}(p) \\
\mathsf{NPSPACE} &= \bigcup_{p \in \mathcal{P}} \text{NSPACE}(p)
\end{align*}
\]
Polynomial complexity class relationships

Theorem (complexity class hierarchy)

\[ P \subseteq NP \subseteq \text{PSPACE} = \text{NPSPACE} \]

Proof.

\( P \subseteq NP \) and \( \text{PSPACE} \subseteq \text{NPSPACE} \) is obvious because deterministic Turing machines are a special case of nondeterministic ones.

\( NP \subseteq \text{NPSPACE} \) holds because a Turing machine can only visit polynomially many tape cells within polynomial time.

\( \text{PSPACE} = \text{NPSPACE} \) is a special case of a classical result known as Savitch’s theorem (Savitch 1970).
The propositional planning problem

Definition (plan existence)
The plan existence problem ($\text{PLANEx}$) is the following decision problem:

**Given:** Planning task $\Pi$
**Question:** Is there a plan for $\Pi$?

$\Rightarrow$ decision problem analogue of satisficing planning

Definition (bounded plan existence)
The bounded plan existence problem ($\text{PLANLen}$) is the following decision problem:

**Given:** Planning task $\Pi$, length bound $K \in \mathbb{N}_0$
**Question:** Is there a plan for $\Pi$ of length at most $K$?

$\Rightarrow$ decision problem analogue of optimal planning
Plan existence vs. bounded plan existence

**Theorem (reduction from PlanEx to PlanLen)**

PlanEx \(\leq_p\) PlanLen

**Proof.**

A propositional planning task with \(n\) state variables has a plan iff it has a plan of length at most \(2^n - 1\).

\(\Rightarrow\) map instance \(\Pi\) of PlanEx to instance \(\langle \Pi, 2^n - 1 \rangle\) of PlanLen, where \(n\) is the number of \(n\) state variables of \(\Pi\)

\(\Rightarrow\) polynomial reduction
Membership in PSPACE

Theorem (PSPACE membership for $\text{PlanLen}$)

$\text{PlanLen} \in \text{PSPACE}$

Proof.

Show $\text{PlanLen} \in \text{NPSPACE}$ and use Savitch’s theorem.

Nondeterministic algorithm:

```python
def plan(⟨A, I, O, G⟩, K):
    s := I
    k := K
    while s \not\models G:
        guess o ∈ O
        fail if o not applicable in s or k = 0
        s := app_o(s)
        k := k - 1
    accept
```
Hardness for PSPACE

Idea: generic reduction

- For an arbitrary fixed DTM $M$ with space bound polynomial $p$ and input $w$, generate planning task which is solvable iff $M$ accepts $w$ in space $p(|w|)$.
- For simplicity, restrict to TMs which never move to the left of the initial head position (no loss of generality).
Reduction: state variables

Let $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$ be the fixed DTM and let $p$ be its space-bound polynomial.

Given input $w_1 \ldots w_n$, define relevant tape positions:

$$X := \{1, \ldots, p(n)\}.$$  

State variables:

- $\text{state}_q$ for all $q \in Q$
- $\text{head}_i$ for all $i \in X \cup \{0, p(n) + 1\}$
- $\text{content}_{i,a}$ for all $i \in X$, $a \in \Sigma_{\square}$

$\rightsquigarrow$ allows encoding a Turing machine configuration.
Reduction: initial state

Let $M = \langle \Sigma, \Box, Q, q_0, q_Y, \delta \rangle$ be the fixed DTM and let $p$ be its space-bound polynomial.

Given input $w_1 \ldots w_n$, define relevant tape positions $X := \{1, \ldots, p(n)\}$.

**Initial state**

Initially true:
- state$q_0$
- head\_1
- content\_i, w\_i for all $i \in \{1, \ldots, n\}$
- content\_i, \Box for all $i \in X \setminus \{1, \ldots, n\}$

Initially false:
- all others
Let $M = \langle \Sigma, \Box, Q, q_0, q_Y, \delta \rangle$ be the fixed DTM and let $p$ be its space-bound polynomial.

Given input $w_1 \ldots w_n$, define relevant tape positions $X := \{1, \ldots, p(n)\}$.

**Operators**

One operator for each transition rule $\delta(q, a) = \langle q', a', \Delta \rangle$ and each cell position $i \in X$:

- **precondition**: $\text{state}_q \land \text{head}_i \land \text{content}_{i,a}$
- **effect**: $\neg \text{state}_q \land \neg \text{head}_i \land \neg \text{content}_{i,a}$
  $\land \text{state}_{q'} \land \text{head}_{i+\Delta} \land \text{content}_{i,a'}$

- If $q = q'$ and/or $a = a'$, omit the effects on $\text{state}_q$ and/or $\text{content}_{i,a}$, to avoid consistency condition issues.
Let $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$ be the fixed DTM and let $p$ be its space-bound polynomial.

Given input $w_1 \ldots w_n$, define relevant tape positions $X := \{1, \ldots, p(n)\}$. 

Goal

$\mathsf{state}_{q_Y}$
PSPACE-completeness for STRIPS plan existence

Theorem (PSPACE-completeness; Bylander, 1994)

PlanEx and PlanLen are PSPACE-complete. This is true even when restricting to STRIPS tasks.

Proof.

Membership for PlanLen was already shown.

Hardness for PlanEx follows because we just presented a polynomial reduction from an arbitrary problem in PSPACE to PlanEx. (Note that the reduction only generates STRIPS tasks.)

Membership for PlanEx and hardness for PlanLen follows from the polynomial reduction from PlanEx to PlanLen.
In addition to the basic complexity result presented in this chapter, there are many special cases, generalizations, variations and related problems studied in the literature:

- **different planning formalisms**
  - e.g., finite-domain representation, nondeterministic effects, partial observability, schematic operators, numerical state variables

- **syntactic restrictions** of planning tasks
  - e.g., without preconditions, without conjunctive effects, STRIPS without delete effects

- **semantic restrictions** of planning task
  - e.g., restricting to certain classes of causal graphs

- **particular planning domains**
  - e.g., Blocksworld, Logistics, FreeCell
Some results for different planning formalisms:

- **FDR tasks:**
  - same complexity as for propositional tasks ("folklore")
  - also true for the SAS+ special case

- **Nondeterministic effects:**
  - fully observable: EXP-complete (Littman, 1997)
  - unobservable: EXPSPACE-complete (Haslum & Jonsson, 1999)
  - partially observable: 2EXP-complete (Rintanen, 2004)

- **Schematic operators:**
  - usually adds one exponential level to PLANEX complexity
  - e.g., classical case EXPSPACE-complete (Erol et al., 1995)

- **Numerical state variables:**
  - undecidable in most variations (Helmert, 2002)
