1 Motivation

Reasoning problems & algorithms

Reasoning problems:
- Satisfiability or subsumption of concept descriptions
- Satisfiability or instance relation in ABoxes

Solving techniques presented in this chapter:
- Structural subsumption algorithms
  - Normalization of concept descriptions and structural comparison
  - Very fast, but can only be used for small DLs
- Tableau algorithms
  - Similar to modal tableau methods
  - Often the method of choice
2 Structural Subsumption Algorithms

Structural subsumption algorithms

In what follows we consider the rather small logic $\mathcal{FL}^-$:

1. $C \sqcap D$
2. $\forall r. C$
3. $\exists r$ (simple existential quantification)

To solve the subsumption problem for this logic we apply the following idea:

1. In the conjunction, collect all universally quantified expressions (also called value restrictions) with the same role and build complex value restriction:

   $\forall r. C \sqcap \forall r. D \rightarrow \forall r. (C \sqcap D)$.

2. Compare all conjuncts with each other.
   For each conjunct in the subsuming concept there should be a corresponding one in the subsumed one.

Example

Example

$D = \text{Human} \sqcap \exists \text{has-child} \sqcap \forall \text{has-child. Human} \sqcap \forall \text{has-child, has-child}$

$C = \text{Human} \sqcap \text{Female} \sqcap \exists \text{has-child} \sqcap \forall \text{has-child. (Human \sqcap \text{Female} \sqcap \exists \text{has-child})}$

Check: $C \sqsubseteq D$

1. Collect value restrictions in $D$:
   ...$\exists \text{has-child. (Human \sqcap \exists \text{has-child})}$$

2. Compare:
   1. For Human in $D$, we have Human in $C$.
   2. For $\exists \text{has-child in } D$, we have $\exists \text{has-child in } C$.
   3. For $\forall \text{has-child(...)}$ in $D$, we have Human and $\exists \text{has-child in } C$.

$\Rightarrow C \sqsubseteq D$!
**Soundness**

**Theorem (Soundness)**

\[ \text{SUB}(C, D) \Rightarrow C \sqsubseteq D \]

**Proof sketch.**

Reordering of terms step (1):

1. Commutativity and associativity are trivial
2. Value restriction law. We show: \((\forall r.(C \cap D))^I = (\forall r.C \cap \forall r.D)^I\)
   Assume \(d \in (\forall r.(C \cap D))^I\).
   If there is no \(e \in D\) with \((d, e) \in r^I\) it follows trivially that \(d \in (\forall r.C \cap \forall r.D)^I\).
   If there is an \(e \in D\) with \((d, e) \in r^I\) it follows \(e \in (C \cap D)^I = C^I \cap D^I\).

Since \(e\) is arbitrary, we have \(d \in (\forall r.C)^I\) and \(d \in (\forall r.D)^I\), i.e., \((\forall r.(C \cap D))^I \subseteq (\forall r.C \cap \forall r.D)^I\).

The other direction is similar.

Steps (2+3+4): Induction on the nesting depth of \(\forall\)-expressions.

---

**Completeness**

**Theorem (Completeness)**

\[ C \sqsubseteq D \Rightarrow \text{SUB}(C, D). \]

**Proof idea.**

One shows the contrapositive:

\[ \neg \text{SUB}(C, D) \Rightarrow C \nsubseteq D \]

Idea: If one of the rules leads to a negative answer, we use this to construct an interpretation with a special element \(d\) such that \(d \in C^I\), but \(d \notin D^I\).

---

**Generalizing the algorithm**

Extensions of \(FL^\neg\) by

- \(\neg A\) (atomic negation),
- \(\leq_{nr}\), \(\geq_{nr}\) (cardinality restrictions),
- \(r \circ s\) (role composition)

do not lead to any problems.

However: If we use full existential restrictions, then it is very unlikely that we can come up with a simple structural subsumption algorithm – having the same flavor as the one above.

More precisely: There is (most probably) no algorithm that uses polynomially many reorderings and simplifications and allows for a simple structural comparison.

Reason: Subsumption for \(FL^\neg + \exists r.C\) is NP-hard (Nutt).

---

**ABox reasoning**

**Idea: Abstraction + classification**

- **Complete** ABox by propagating value restrictions to role fillers.
- Compute for each object its most specialized concepts.
- These can then be handled using the ordinary subsumption algorithm.
### Tableau Subsumption Method

- **Example**
- **Reductions:** Unfolding & Unsatisfiability
- **Model Construction**
- **Equivalences & NNF**
- **Constraint Systems**
- **Transforming Constraint Systems**
- **Invariances**
- **Soundness and Completeness**
- **Space Complexity**
- **ABox Reasoning**

### Tableau Subsumption Method

- **Example**
- **Reductions:** Unfolding & Unsatisfiability
- **Model Construction**
- **Equivalences & NNF**
- **Constraint Systems**
- **Transforming Constraint Systems**
- **Invariances**
- **Soundness and Completeness**
- **Space Complexity**
- **ABox Reasoning**

### Example: Subsumption in a TBox

**TBox:**

- **Hermaphrodite**: Male $\sqcap$ Female
- **Parents-of-sons-and-daughters**: 
  \[ \exists \text{has-child}.\text{Male} \sqcap \exists \text{has-child}.\text{Female} \]
- **Parents-of-hermaphrodite**: 
  \[ \exists \text{has-child}.\text{Hermaphrodite} \]

**Query:**

- **Parents-of-sons-and-daughters**: $\subseteq_T$
- **Parents-of-hermaphrodites**

### Logic $\mathcal{ALC}$:

- \( C \sqcap D \)
- \( C \sqcup D \)
- \( \neg C \)
- \( \forall r.C \)
- \( \exists r.C \)

**Idea:** Decide (un-)satisfiability of a concept description $C$ by trying to systematically construct a model for $C$. If that is successful, $C$ is satisfiable. Otherwise, $C$ is unsatisfiable.

### Reductions

1. **Unfolding:**
   \[ \exists \text{has-child}.\text{Male} \sqcap \exists \text{has-child}.\text{Female} \sqsubseteq \exists \text{has-child}.(\text{Male} \sqcap \text{Female}) \]

2. **Reduction to unsatisfiability:** Is the concept
   \[ \exists \text{has-child}.\text{Male} \sqcap \exists \text{has-child}.\text{Female} \sqcap \neg \exists \text{has-child}(\text{Male} \sqcap \text{Female}) \]
   unsatisfiable?

3. **Negation normal form (move negations inside):**
   \[ \exists \text{has-child}.\text{Male} \sqcap \exists \text{has-child}.\text{Female} \sqcap \exists \text{has-child}.(\neg \text{Male} \sqcup \neg \text{Female}) \]

4. **Try to construct a model**
Assumption: There exists an object \( x \) in the interpretation of our concept:
\[
x \in (\exists \ldots)^I
\]
This implies that \( x \) is in the interpretation of all conjuncts:
\[
x \in (\exists \text{has-child.Male})^I
x \in (\exists \text{has-child.Female})^I
x \in (\forall \text{has-child.(¬Male ⊔ ¬Female)})^I
\]
This implies that there should be objects \( y \) and \( z \) such that \((x,y)\in \text{has-child}^I, (x,z)\in \text{has-child}^I, y \in \text{Male}^I\) and \( z \in \text{Female}^I\), and...

\[\begin{align*}
\text{Model construction (2)}
\end{align*}\]

\[\begin{align*}
x : \exists \text{has-child.Male} \\
x : \exists \text{has-child.Female} \\
\end{align*}\]
Model construction (5)

\[
\begin{align*}
  x : & \exists \text{has-child}.\text{Male} \\
  x : & \exists \text{has-child}.\text{Female} \\
  x : & \forall \text{has-child}.(\neg \text{Male} \sqcup \neg \text{Female}) \\
  y : & \neg \text{Female} \\
  z : & \neg \text{Male} \\
\end{align*}
\]

~⇒ Model constructed!

January 25, 2013 Nebel, Wölfl, Hué – KRR 24 / 34

Tableau method (1): NNF

We write: \( C \equiv D \) iff \( C \sqsubseteq D \) and \( D \sqsubseteq C \). Now we have the following equivalences:

\[
\begin{align*}
  \neg(C \sqcap D) & \equiv \neg C \sqcup \neg D \\
  \neg(\forall r.C) & \equiv \exists r.\neg C \\
  \neg(\exists r.C) & \equiv \forall r.\neg C \\
  \neg \neg C & \equiv C
\end{align*}
\]

These equivalences can be used to move all negations signs to the inside, resulting in concept description where only concept names are negated: negation normal form (NNF).

**Theorem (NNF)**

The negation normal form of an ALC concept can be computed in polynomial time.

Tableau method (2): Constraint systems

A **constraint** is a syntactical object of the form:

\[
x : C \quad \text{or} \quad x r y,
\]

where \( C \) is a concept description in NNF, \( r \) is a role name, and \( x \) and \( y \) are **variable names**.

Let \( I \) be an interpretation with universe \( D \). An **I-assignment** \( \alpha \) is a function that maps each variable symbol to an object of the universe \( D \).

A constraint \( x : C (x r y) \) is **satisfied** by an \( I \)-assignment \( \alpha \) if \( \alpha(x) \in C I \) (resp. \( \alpha(x), \alpha(y) \in r I \)).

January 25, 2013 Nebel, Wölfl, Hué – KRR 26 / 34

Tableau method (3): Constraint systems

**Definition**

A **constraint system** \( S \) is a finite, non-empty set of constraints. An \( I \)-assignment \( \alpha \) **satisfies** \( S \) if \( \alpha \) satisfies each constraint in \( S \). \( S \) is **satisfiable** if there exist \( I \) and \( \alpha \) such that \( \alpha \) satisfies \( S \).

**Theorem**

An ALC concept \( C \) in NNF is satisfiable if and only if the system \( \{ x : C \} \) is satisfiable.

January 25, 2013 Nebel, Wölfl, Hué – KRR 27 / 34
Tableau method (4): Transforming constraint systems

A constraint system is called closed if no transformation rule can be applied.

A clash is a pair of constraints of the form \( x : A \) and \( x : \neg A \), where \( A \) is a concept name.

**Theorem (Soundness and Completeness)**

A closed constraint system is satisfiable if and only if it does not contain a clash.

**Proof idea.**

\( \Rightarrow \): obvious. \( \Leftarrow \): Construct a model by using the concept labels.

Tableau method (5): Invariances

**Theorem (Invariance)**

Let \( S \) and \( T \) be constraint systems.

1. If \( T \) has been generated by applying a deterministic rule to \( S \), then \( S \) is satisfiable if and only if \( T \) is satisfiable.
2. If \( T \) has been generated by applying a non-deterministic rule to \( S \), then \( S \) is satisfiable if \( T \) is satisfiable.

Furthermore, if a non-deterministic rule can be applied to \( S \), then it can be applied such that \( S \) is satisfiable if and only if the resulting system \( T \) is satisfiable.

**Theorem (Termination)**

Let \( C \) be an \( ALC \) concept description in NNF. Then there exists no infinite chain of transformations starting from the constraint system \( \{ x : C \} \).

Space requirements

Because the tableau method is non-deterministic (\( \rightarrow_\cup \) rule), there could be exponentially many closed constraint systems in the end.

Interestingly, applying the rules on a single constraint system can lead to constraint systems of exponential size.

**Example**

\[
\forall r.A \land \forall r.B \land \\
\forall r.\left( \exists r.A \land \exists r.B \land \\
\forall r.\left( \exists r.A \land \exists r.B \land \\
\forall r.\left( \ldots \right) \right) \right)
\]

**However:** One can modify the algorithm so that it needs only polynomial space.

**Idea:** Generate a \( y \) only for one \( \exists r.C \) and then proceed into the depth.
ABox reasoning

ABox satisfiability can also be decided using the tableau method if we can add constraints of the form $x \neq y$ (for UNA):

- Normalize and unfold and add inequalities for all pairs of objects mentioned in the ABox.
- Strictly speaking, in $\mathcal{ALC}$ we do not need this because we are never forced to identify two objects.
