in TBoxes

Outlook

Literature

L_2 is the fragment of first-order predicate logic using only two different variable names (**note**: variable names can be reused!).

$L_2^=$: L_2 plus equality.

Theorem

$L_2^=$ is decidable.

Corollary

Subsumption and satisfiability of concept descriptions is decidable in description logics using only the following concept and role forming operators: $C \sqcap D$, $C \sqcup D$, $\neg C$, $\forall r.C$, $\exists r.C$, $r \sqsubseteq s$, $r \sqcap s$, $r \sqcup s$, $\neg r$, r^{-1} .

Potential problems: Role composition and cardinality restrictions for role fillers. Cardinality restrictions, however, are not a real problem.

How hard is \mathcal{ALC} subsumption?

Proposition

\mathcal{ALC} subsumption and unsatisfiability are co-NP-hard.

Proof.

Unsatisfiability and subsumption are reducible to each other. We give a reduction from UNSAT. A propositional formula φ over the atoms a_i is mapped to $\pi(\varphi)$:

$$a_i \mapsto a_i$$

$$\psi \wedge \psi' \mapsto \pi(\psi) \sqcap \pi(\psi')$$

$$\psi' \vee \psi \mapsto \pi(\psi) \sqcup \pi(\psi')$$

$$\neg \psi \mapsto \neg \pi(\psi)$$

Obviously, φ is satisfiable iff $\pi(\varphi)$ is satisfiable (use structural induction). If φ has a model, construct a model for $\pi(\varphi)$ with just one element t standing for the truth of the atoms and the formula.

Conversely, if $\pi(\varphi)$ satisfiable, pick one element $d \in \pi(\varphi)^{\mathcal{I}}$ and set the truth value of atom a_i according to the fact that $d \in \pi(a_i)^{\mathcal{I}}$. \square

Lemma (Lower bound for \mathcal{ALC})

\mathcal{ALC} subsumption, unsatisfiability and satisfiability are all PSPACE-hard.

Proof.

Extend the reduction given in the last proof by the following two rules – assuming that b is a fixed role name:

$$\Box\psi \mapsto \forall b.\pi(\psi)$$

$$\Diamond\psi \mapsto \exists b.\pi(\psi)$$

Again, obviously, φ is satisfiable iff $\pi(\varphi)$ is satisfiable (again using structural induction). If φ has a Kripke model, interpret each world w as an object in the universe of discourse, that is, w is an instance of the primitive concept $\pi(a_i)$ iff a_i is true in w . For the converse direction use the interpretation the other way around. \square

Further consequences of the reducibility of K to \mathcal{ALC}

- In the reduction we used only **one** role symbol. Are there modal logics that would require more than one such role symbol?
 - ↪ The **multi-modal logic** K_n has n different Box operators \Box_i (for n different agents).
 - ↪ \mathcal{ALC} (wrt. TBox reasoning) is a **notational variant** of K_n . [Schild, IJCAI-91]
- Are there other modal logics that correspond to other descriptions logics?
 - ↪ **propositional dynamic logic** (PDL), e.g., transitive closure, composition, role inverse, ...

- Of course, one wants to have a description logic with high **expressive power**. However, high expressive power implies usually that the **computational complexity** of the reasoning problems might also be high, e.g., \mathcal{FL}^- vs. \mathcal{ALC} .
- Does it make sense to use languages such as \mathcal{ALC} or even extensions (corresponding to PDL) with higher complexity?
- There are three approaches to this problem:
 - 1 Use only **small** description logics with **complete** inference algorithms.
 - 2 Use **expressive** description logics, but employ **incomplete** inference algorithms.
 - 3 Use **expressive** description logics with **complete** inference algorithms.
- For a long time, only options 1 and 2 were studied. Meanwhile, most researcher concentrate on **option 3**!

Is subsumption in the empty TBox enough?

- We have shown that we can **reduce** concept subsumption in a given TBox to concept subsumption in the empty TBox.
- However, it is not obvious that this can be done in **polynomial time** ...
- In the following example **unfolding** leads to an exponential blowup:

$$C_1 \doteq \forall r.C_0 \sqcap \forall s.C_0$$

$$C_2 \doteq \forall r.C_1 \sqcap \forall s.C_1$$

$$\vdots$$

$$C_n \doteq \forall r.C_{n-1} \sqcap \forall s.C_{n-1}$$

- Unfolding C_n leads to a concept description with a size $\Omega(2^n)$.
- Is it possible to **avoid** this blowup? Can we avoid exponential preprocessing?

Complexity of TBox subsumption

Theorem (Complexity of TBox subsumption)

TBox subsumption for \mathcal{FL}_0 is NP-hard.

Proof sketch.

We use the NDFA-equivalence problem, which is NP-complete for cycle-free automata and PSPACE-complete for general NDFAs. We transform a cycle-free NDFA to a \mathcal{FL}_0 -terminology with the mapping π as follows:

automaton $A \mapsto$ terminology \mathcal{T}_A

state $q \mapsto$ concept name q

terminal state $q_f \mapsto$ concept name q_f

input symbol $r \mapsto$ role name r

r -transition from q to $q' \mapsto q \sqsubseteq \dots \sqcap \forall r : q' \sqcap \dots$

What does this complexity result mean?

- Note that for expressive languages such as \mathcal{ALC} , we do not notice any difference!
- The TBox subsumption complexity result for less expressive languages does not play a large role in practice
- Pathological situations do not happen very often.
- In fact, if the definition depth is logarithmic in the size of the TBox, the whole problem vanishes.
- However, in order to protect oneself against such problems, one often uses lazy unfolding ...
- Similarly, also for \mathcal{ALC} concept descriptions, one notices that they are usually very well behaved.

- In fact, if the definition depth is logarithmic in the size of the TBox, the whole problem vanishes.
- However, in order to protect oneself against such problems, one often uses **lazy unfolding** ...
- Similarly, also for \mathcal{ALC} concept descriptions, one notices that they are usually very well behaved.

Outlook

Literature

- Description logics have a long history (Tarski's relation algebras and Brachman's KL-ONE).
- Early on, either small languages with provably easy reasoning problems (e.g., the system **CLASSIC**) or large languages with incomplete inference algorithms (e.g., the system **Loom**) were used.
- Meanwhile, one uses complete algorithms on very large descriptions logics (e.g., **SHIQ**), e.g., in the systems **FaCT++** and **RACER**.
- Nowadays tools can handle KBs with up to 160,000 concepts (example from **unified medical language system**) in reasonable time.
- Description logics are used as the semantic backbone for **OWL** (a Web-language extending RDF).
