

A simple heuristic for deterministic planning

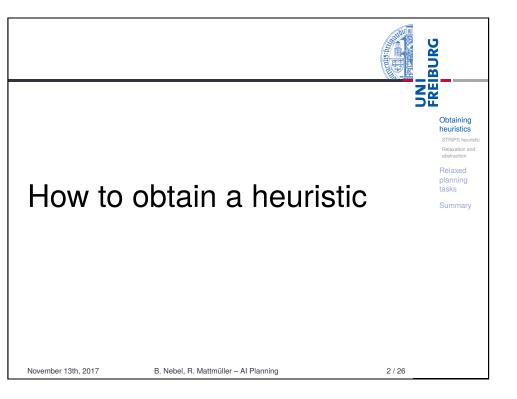

STRIPS (Fikes & Nilsson, 1971) used the number of state variables that differ in current state *s* and a STRIPS goal  $a_1 \land \dots \land a_n$ :

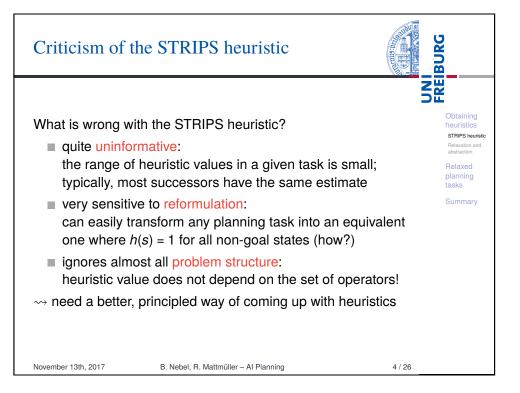

$$h(s) := |\{i \in \{1, ..., n\} \mid s \not\models a_i\}|.$$

Intuition: more true goal literals ~>> closer to the goal

→ STRIPS heuristic (a.k.a. goal-count heuristic) (properties?)

Note: From now on, for convenience we usually write heuristics as functions of states (as above), not nodes. Node heuristic h' is defined from state heuristic h as  $h'(\sigma) := h(state(\sigma))$ .

tasks

Summary

How do we relax a problem?

### Example (Route planning for a road network)

The road network is formalized as a weighted graph over points in the Euclidean plane. The weight of an edge is the road distance between two locations.

A relaxation drops constraints of the original problem.

Example (Relaxation for route planning)

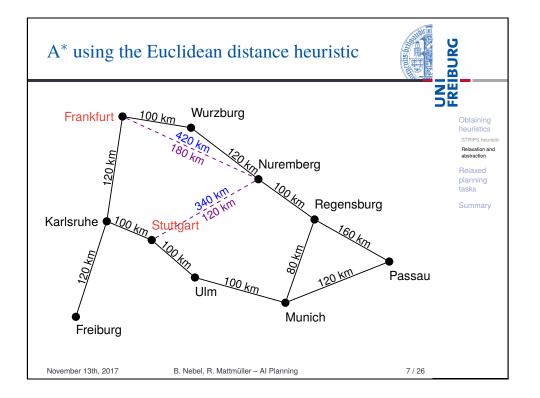

Use the Euclidean distance  $\sqrt{|x_1 - x_2|^2 + |y_1 - y_2|^2}$  as a heuristic for the road distance between  $\langle x_1, y_1 \rangle$  and  $\langle x_2, y_2 \rangle$ This is a lower bound on the road distance (~> admissible).

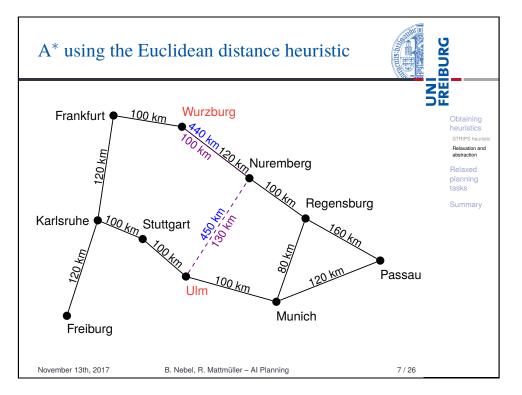

~ We drop the constraint of having to travel on roads.

The relaxation lemma Greedy algorit

### Definition (relaxation of operators)

The relaxation  $o^+$  of an operator  $o = \langle \chi, e \rangle$  in positive normal form is the operator which is obtained by replacing all negative effects  $\neg a$  within *e* by the do-nothing effect  $\top$ .

### Definition (relaxation of planning tasks)

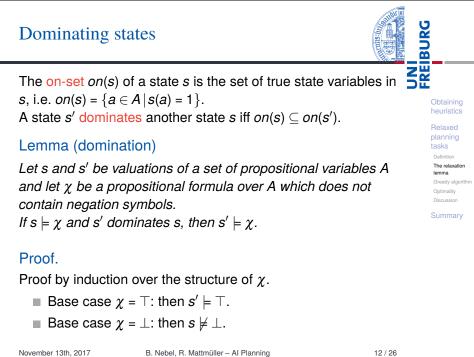

The relaxation  $\Pi^+$  of a planning task  $\Pi = \langle A, I, O, \gamma \rangle$  in positive normal form is the planning task  $\Pi^+ := \langle A, I, \{o^+ \mid o \in O\}, \gamma \rangle$ .

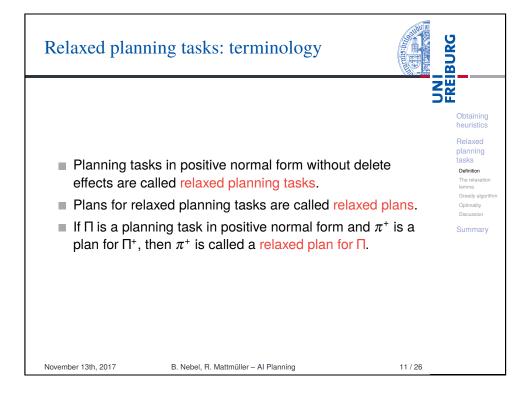

#### Definition (relaxation of operator sequences)

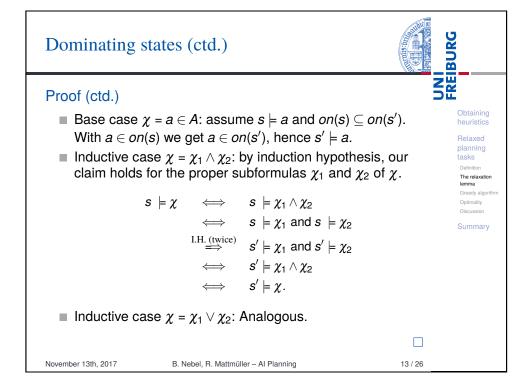

```
The relaxation of an operator sequence \pi = o_1 \dots o_n is the
operator sequence \pi^+ := o_1^+ \dots o_n^+.
```

The relaxation lemma

Optimality

Discussion

For the rest of this chapter, we assume that all planning tasks are in positive normal form.

### Lemma (relaxation)

Let s be a state. let s' be a state that dominates s. and let  $\pi$  be an operator sequence which is applicable in s. Then  $\pi^+$  is applicable in s' and  $app_{\pi^+}(s')$  dominates  $app_{\pi}(s)$ . Moreover, if  $\pi$  leads to a goal state from s, then  $\pi^+$  leads to a goal state from s'.

#### Proof.

The "moreover" part follows from the rest by the domination lemma. Prove the rest by induction over the length of  $\pi$ .

#### Base case: $\pi = \varepsilon$

$app_{\pi^+}(s') = s'.$ Do	minates $app_{\pi}(s) = s$ by assumption.	
November 13th 2017	B Nebel B Mattmüller – Al Planning	

## Consequences of the relaxation lemma

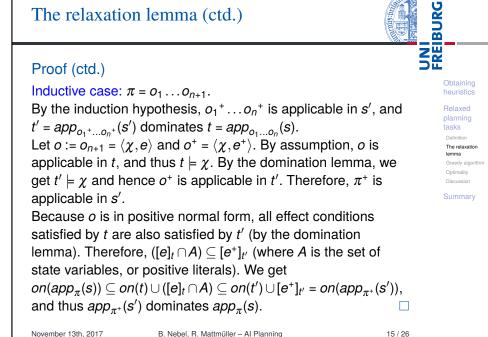

Let  $\pi$  be an operator sequence that is applicable in state s. Then  $\pi^+$  is applicable in s and  $app_{\pi^+}(s)$  dominates  $app_{\pi}(s)$ . If  $\pi$  is a plan for  $\Pi$ , then  $\pi^+$  is a plan for  $\Pi^+$ .

### Proof.

Apply relaxation lemma with s' = s.

- Relaxations of plans are relaxed plans.
- Relaxations are no harder to solve than original task.
- Optimal relaxed plans are never longer than optimal plans  $\sim \rightarrow$ for original tasks.

Consequences of the relaxation lemma (ctd.)

The relaxation lemma (ctd.)

#### Corollary (relaxation preserves dominance)

Let s be a state. let s' be a state that dominates s. and let  $\pi^+$  be a relaxed operator sequence applicable in s. Then  $\pi^+$  is applicable in s' and  $app_{\pi^+}(s')$  dominates  $app_{\pi^+}(s)$ .

#### Proof.

Apply relaxation lemma with  $\pi^+$  for  $\pi$ , noting that  $(\pi^+)^+ = \pi^+$ .

Obtaining planning tasks The relaxation lemma Optimality Summarv

UNI FREIBURG

- $\rightarrow$  If there is a relaxed plan starting from state s, the same plan can be used starting from a dominating state s'.
- → Making a transition to a dominating state never hurts in relaxed planning tasks.

## Monotonicity of relaxed planning tasks

We need one final property before we can provide an algorithm for solving relaxed planning tasks.

#### Lemma (monotonicity)

Let  $o^+ = \langle \chi, e^+ \rangle$  be a relaxed operator and let s be a state in which o<sup>+</sup> is applicable. Then  $app_{o^+}(s)$  dominates s.

Optimality

Summarv

Greedy algorithr

BURG

#### Proof.

Since relaxed operators only have positive effects, we have  $on(s) \subseteq on(s) \cup [e^+]_s = on(app_{o^+}(s)).$ 

Together with our previous results, this means that making a transition in a relaxed planning task never hurts.

# Correctness of the greedy algorithm

#### The algorithm is sound:

If it returns a plan, this is indeed a correct solution.

- If it returns "unsolvable", the task is indeed unsolvable
  - Upon termination, there clearly is no relaxed plan from s.
  - By iterated application of the monotonicity lemma, s dominates *I*.
  - By the relaxation lemma, there is no solution from *I*.

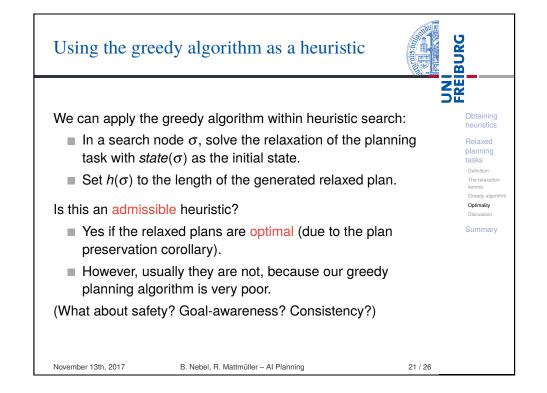

What about completeness (termination) and runtime?

- Each iteration of the loop adds at least one atom to on(s).
- This guarantees termination after at most |A| iterations.
- Thus, the algorithm can clearly be implemented to run in polynomial time.
  - A good implementation runs in  $O(||\Pi||)$ .

## The set cover problem

To obtain an admissible heuristic, we need to generate optimal relaxed plans. Can we do this efficiently? This question is related to the following problem:

BURG

Obtaining heuristics

Relaxed

tasks

lemma

Optimality

Discussion

22/26

### Problem (set cover)

Given: a finite set U, a collection of subsets  $C = \{C_1, ..., C_n\}$ with  $C_i \subseteq U$  for all  $i \in \{1, ..., n\}$ , and a natural number K. Question: Does there exist a set cover of size at most K, i. e., a subcollection  $S = \{S_1, ..., S_m\} \subseteq C$  with  $S_1 \cup \cdots \cup S_m = U$  and  $m \leq K$ ?

The following is a classical result from complexity theory:

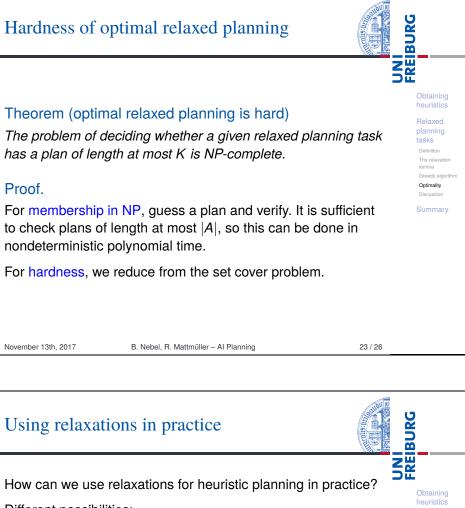

### Theorem (Karp 1972)

The set cover problem is NP-complete.

November 13th, 2017

B. Nebel, R. Mattmüller – Al Planning

#### UNI FREIBURG Hardness of optimal relaxed planning (ctd.) Proof (ctd.) Obtaining Given a set cover instance $\langle U, C, K \rangle$ , we generate the heuristics following relaxed planning task $\Pi^+ = \langle A, I, O^+, \gamma \rangle$ : A = Utasks $\blacksquare I = \{a \mapsto 0 \mid a \in A\}$ lemma $O^+ = \{ \langle \top, \bigwedge_{a \in C_i} a \rangle \mid C_i \in C \}$ Optimality $\gamma = \bigwedge_{a \in II} a$ If *S* is a set cover, the corresponding operators form a plan. Conversely, each plan induces a set cover by taking the subsets corresponding to the operators. There exists a plan of length at most K iff there exists a set cover of size K. Moreover, $\Pi^+$ can be generated from the set cover instance in polynomial time, so this is a polynomial reduction. November 13th, 2017 B. Nebel, R. Mattmüller - Al Planning 24 / 26

Different possibilities:

Implement an optimal planner for relaxed planning tasks and use its solution lengths as an estimate, even though it is NP-hard.

 $\rightsquigarrow h^+$  heuristic

- Do not actually solve the relaxed planning task, but compute an estimate of its difficulty in a different way.

   *h*<sub>max</sub> heuristic, *h*<sub>add</sub> heuristic, *h*<sub>LM-cut</sub> heuristic
- Compute a solution for relaxed planning tasks which is not necessarily optimal, but "reasonable".
   ~> h<sub>FF</sub> heuristic
