Relaxation
heuristics
Summary

## Towards better relaxed plans

Why does the greedy algorithm compute low-quality plans?

- It may apply many operators which are not goal-directed.

How can this problem be fixed?

- Reaching the goal of a relaxed planning task is most easily achieved with forward search.
- Analyzing relevance of an operator for achieving a goal (or subgoal) is most easily achieved with backward search.

Idea: Use a forward-backward algorithm that first finds a path to the goal greedily, then prunes it to a relevant subplan.

## Relaxed plan steps

How to decide which operators to apply in forward direction?

- We avoid such a decision by applying all applicable operators simultaneously.

## Definition (plan step)

A plan step is a set of operators $\omega=\left\{\left\langle\chi_{1}, e_{1}\right\rangle, \ldots,\left\langle\chi_{n}, e_{n}\right\rangle\right\}$. In the special case of all operators of $\omega$ being relaxed,

Parallel we further define:

- Plan step $\omega$ is applicable in state $s$ iff $s=\chi_{i}$ for all $i \in\{1, \ldots, n\}$.
- The result of applying $\omega$ to $s$, in symbols $\operatorname{app}_{\omega}(s)$, is defined as the state $s^{\prime}$ with on $\left(s^{\prime}\right)=o n(s) \cup \bigcup_{i=1}^{n}\left[e_{i}\right]_{s}$.
general semantics for plan steps $\rightsquigarrow$ much later

## Applying relaxed plan steps: examples

In all cases, $s=\{a \mapsto 0, b \mapsto 0, c \mapsto 1, d \mapsto 0\}$.
$\square \omega=\{\langle c, a\rangle,\langle T, b\rangle\}$
$\square \omega=\{\langle c, a\rangle,\langle c, a \triangleright b\rangle\}$
$\omega=\{\langle c, a \wedge b\rangle,\langle a, b \triangleright d\rangle\}$
$\square \omega=\{\langle c, a \wedge(b \triangleright d)\rangle,\langle c, b \wedge(a \triangleright d)\rangle\}$

planning
graphs
Relaxation
heuristics
Summary

## Serializations

Applying a relaxed plan step to a state is related to applying the operators in the step to a state in sequence.

Parallel
Definition (serialization)
A serialization of plan step $\omega=\left\{o_{1}^{+}, \ldots, o_{n}^{+}\right\}$is a sequence $o_{\pi(1)}^{+}, \ldots, o_{\pi(n)}^{+}$where $\pi$ is a permutation of $\{1, \ldots, n\}$.

## Lemma (conservativeness of plan step semantics)

If $\omega$ is a plan step applicable in a state s of a relaxed planning task, then each serialization $o_{1}, \ldots, o_{n}$ of $\omega$ is applicable in $s$ and $a p p_{o_{1}, \ldots, o_{n}}(s)$ dominates $\operatorname{app}_{\omega}(s)$.

- Does equality hold for all/some serialization(s)?
- What if there are no conditional effects?
- What if we allowed general (unrelaxed) planning tasks?

## Parallel plans

## Definition (parallel plan)

A parallel plan for a relaxed planning task $\left\langle A, I, O^{+}, \gamma\right\rangle$ is a sequence of plan steps $\omega_{1}, \ldots, \omega_{n}$ of operators in $O^{+}$with:

- $s_{0}:=1$
- For $i=1, \ldots, n$, step $\omega_{i}$ is applicable in $s_{i-1}$
and $s_{i}:=\operatorname{app}_{\omega_{i}}\left(s_{i-1}\right)$.
- $s_{n}=\gamma$

Remark: By ordering the operators within each single step arbitrarily, we obtain a (regular, non-parallel) plan.

Idea: In the forward phase of the heuristic computation,
1 apply plan step with all operators applicable initially,
2 apply plan step with all operators applicable then,
3 and so on.

## Definition (forward state/plan step/set)

Let $\Pi^{+}=\left\langle A, I, O^{+}, \gamma\right\rangle$ be a relaxed planning task.
The $n$-th forward state, in symbols $s_{n}^{F}\left(n \in \mathbb{N}_{0}\right)$, the $n$-th forward plan step, in symbols $\omega_{n}^{F}\left(n \in \mathbb{N}_{1}\right)$, and the $n$-th forward set, in symbols $S_{n}^{F}\left(n \in \mathbb{N}_{0}\right)$, are defined as:
$-s_{0}^{F}:=I$
$\omega_{n}^{\mathrm{F}}:=\left\{0 \in O^{+} \mid 0\right.$ applicable in $\left.s_{n-1}^{\mathrm{F}}\right\}$ for all $n \in \mathbb{N}_{1}$
$s_{n}^{F}:=\operatorname{app}_{\omega_{n}^{F}}\left(s_{n-1}^{F}\right)$ for all $n \in \mathbb{N}_{1}$

- $S_{n}^{\mathrm{F}}:=$ on $\left(s_{n}^{\mathrm{F}}\right)$ for all $n \in \mathbb{N}_{0}$

The max heuristic $h_{\max }$

## Definition (parallel forward distance)

The parallel forward distance of a relaxed planning task $\left\langle A, I, O^{+}, \gamma\right\rangle$ is the lowest number $n \in \mathbb{N}_{0}$ such that $s_{n}^{F}=\gamma$, or $\infty$ if no forward state satisfies $\gamma$.

Remark: The parallel forward distance can be computed in polynomial time. (How?)

Parallel
plans
Plan steps
Forward distances
Relaxed
planning

## Definition (max heuristic $h_{\text {max }}$ )

Let $\Pi=\langle A, I, O, \gamma\rangle$ be a planning task in positive normal form, and let $s$ be a state of $\Pi$.
The max heuristic estimate for $s, h_{\max }(s)$, is the parallel forward distance of the relaxed planning task $\left\langle A, s, O^{+}, \gamma\right\rangle$.

Remark: $h_{\text {max }}$ is safe, goal-aware, admissible and consistent. (Why?)

## So far, so good...

Parallel
plans
Plan steps
Forward distances

- We have seen how systematic computation of forward states leads to an admissible heuristic estimate.
- However, this estimate is very coarse.
- To improve it, we need to include backward propagation of information.

For this purpose, we use so-called relaxed planning graphs.

## Relaxed planning graphs

## AND/OR dags

## Definition (AND/OR dag)

An AND/OR dag $\langle V, A$, type $\rangle$ is a directed acyclic graph $\langle V, A\rangle$ with a label function type: $V \rightarrow\{\wedge, \vee\}$ partitioning nodes into AND nodes $($ type $(v)=\wedge)$ and OR nodes (type $(v)=\vee)$.

Parallel plans

Let $G=\langle V, A$, type $\rangle$ be an AND/OR dag, and let $u \in V$ be a node with successor set $\left\{v_{1}, \ldots, v_{k}\right\} \subseteq V$.
The (truth) value of $u$, val( $(u)$, is inductively defined as:

- If type $(u)=\wedge$, then $\operatorname{val}(u)=\operatorname{val}\left(v_{1}\right) \wedge \cdots \wedge \operatorname{val}\left(v_{k}\right)$.
- If $\operatorname{type}(u)=\vee$, then $\operatorname{val}(u)=\operatorname{val}\left(v_{1}\right) \vee \cdots \vee \operatorname{val}\left(v_{k}\right)$.

## Relaxed planning graphs

Let $\Pi^{+}$be a relaxed planning task, and let $k \in \mathbb{N}_{0}$.
The relaxed planning graph of $\Pi^{+}$for depth $k$, in symbols

- which propositions can be made true in $k$ plan steps, and
- how they can be made true.

Its construction is a bit involved, so we present it in stages.

## Running example

As a running example, consider the relaxed planning task $\left\langle A, I,\left\{o_{1}, o_{2}, o_{3}, o_{4}\right\}, \gamma\right\rangle$ with

$$
\begin{aligned}
A= & \{a, b, c, d, e, f, g, h\} \\
I= & \{a \mapsto 1, b \mapsto 0, c \mapsto 1, d \mapsto 1, \\
& e \mapsto 0, f \mapsto 0, g \mapsto 0, h \mapsto 0\} \\
o_{1}= & \langle b \vee(c \wedge d), b \wedge((a \wedge b) \triangleright e)\rangle \\
o_{2}= & \langle\top, f\rangle \\
o_{3}= & \langle f, g\rangle \\
o_{4}= & \langle f, h\rangle \\
\gamma= & e \wedge(g \wedge h)
\end{aligned}
$$

Parallel

## Running example: forward sets and plan steps

$$
\begin{aligned}
& I=\{a \mapsto 1, b \mapsto 0, c \mapsto 1, d \mapsto 1, e \mapsto 0, f \mapsto 0, g \mapsto 0, h \mapsto 0\} \\
& o_{1}=\langle b \vee(c \wedge d), b \wedge((a \wedge b) \triangleright e)\rangle \\
& o_{2}=\langle\top, f\rangle, \quad o_{3}=\langle f, g\rangle, \quad o_{4}=\langle f, h\rangle \\
& S_{0}^{F}=\{a, c, d\} \\
& \omega_{1}^{F}=\left\{o_{1}, o_{2}\right\} \\
& S_{1}^{F}=\{a, b, c, d, f\} \\
& \omega_{2}^{F}=\left\{o_{1}, o_{2}, o_{3}, o_{4}\right\} \\
& S_{2}^{F}=\{a, b, c, d, e, f, g, h\} \\
& \omega_{3}^{F}=\omega_{2}^{F} \\
& S_{3}^{F}=S_{2}^{F} \text { etc. }
\end{aligned}
$$

Parallel
plans
Relaxed
planning
graphs
Introduction
Construction

## Components of relaxed planning graphs

A relaxed planning graph consists of four kinds of components:

- Proposition nodes represent the truth value of propositions after applying a certain number of plan steps.
- Idle arcs represent the fact that state variables, once true, remain true.
- Operator subgraphs represent the possibility and effect of applying a given operator in a given plan step.
- The goal subgraph represents the truth value of the goal condition after $k$ plan steps.

## Relaxed planning graph: proposition layers

Let $\Pi^{+}=\left\langle A, I, O^{+}, \gamma\right\rangle$ be a relaxed planning task, let $k \in \mathbb{N}_{0}$.
For each $i \in\{0, \ldots, k\}, R P G_{k}\left(\Pi^{+}\right)$contains one proposition
Parallel
layer which consists of:

- a proposition node $a^{i}$ for each state variable $a \in A$.

Node $a^{i}$ is an AND node if $i=0$ and $I=a$.
Otherwise, it is an OR node.

## Relaxed planning graph: idle arcs

For each proposition node $a^{i}$ with $i \in\{1, \ldots, k\}, R P G_{k}\left(\Pi^{+}\right)$

Intuition: If a state variable is true in step $i$, one of the possible reasons is that it was already previously true.

## Relaxed planning graph: idle arcs

## Relaxed planning graph: idle arcs

## Relaxed planning graph: operator subgraphs

For each $i \in\{1, \ldots, k\}$ and each operator $o^{+}=\left\langle\chi, e^{+}\right\rangle \in O^{+}$, $R P G_{k}\left(\Pi^{+}\right)$contains a subgraph called an operator subgraph with the following parts:

- one formula node $n_{\varphi}^{i}$ for each formula $\varphi$ which is a subformula of $\chi$ or of some effect condition in $e^{+}$:
$\square$ If $\varphi=a$ for some atom $a, n_{\varphi}^{i}$ is the proposition node $a^{i-1}$.

Parallel

- If $\varphi=\perp, n_{\varphi}^{i}$ is a new OR node without outgoing arcs.
- If $\varphi=\left(\varphi^{\prime} \wedge \varphi^{\prime \prime}\right), n_{\varphi}^{i}$ is a new AND node with outgoing arcs to $n_{\varphi^{\prime}}^{i}$ and $n_{\varphi^{\prime \prime}}^{i}$.
- If $\varphi=\left(\varphi^{\prime} \vee \varphi^{\prime \prime}\right), n_{\varphi}^{i}$ is a new OR node with outgoing arcs to $n_{\varphi^{\prime}}^{i}$ and $n_{\varphi^{\prime \prime}}^{i}$.

## Relaxed planning graph: operator subgraphs

For each $i \in\{1, \ldots, k\}$ and each operator $o^{+}=\left\langle\chi, e^{+}\right\rangle \in O^{+}$, $R P G_{k}\left(\Pi^{+}\right)$contains a subgraph called an operator subgraph with the following parts:

- for each conditional effect ( $\chi^{\prime} \triangleright a$ ) in $e^{+}$, an effect node $o_{\chi^{\prime}}^{i}$ (an AND node) with outgoing arcs to the precondition formula node $n_{\chi}^{i}$ and effect condition formula node $n_{\chi^{\prime}}^{i}$, and incoming arc from proposition node $a^{i}$
- unconditional effects a (effects which are not part of a conditional effect) are treated the same, except that there is no arc to an effect condition formula node
- effects with identical condition (including groups of unconditional effects) share the same effect node
- the effect node for unconditional effects is denoted by $o^{i}$

Operator subgraph for $o_{1}=\langle b \vee(c \wedge d), b \wedge((a \wedge b) \triangleright e)\rangle$ for layer $i=1$.

Theorem (relaxed planning graph truth values)
Let $\Pi^{+}=\left\langle A, I, O^{+}, \gamma\right\rangle$ be a relaxed planning task.
Then the truth values of the nodes of its depth-k relaxed planning graph $R P G_{k}\left(\Pi^{+}\right)$relate to the forward sets and forward plan steps of $\Pi^{+}$as follows:

- Proposition nodes:

For all $a \in A$ and $i \in\{0, \ldots, k\}$, val $\left(a^{i}\right)=1$ iff $a \in S_{i}^{F}$.

- (Unconditional) effect nodes:

For all $o \in O^{+}$and $i \in\{1, \ldots, k\}$, val( $\left.o^{i}\right)=1$ iff $o \in \omega_{i}^{F}$.

- Goal nodes: val( $\left.n_{\gamma}^{k}\right)=1$ iff the parallel forward distance of $\Pi^{+}$is at most $k$.
(We omit the straight-forward proof.)

## Relaxed planning graphs for STRIPS

Remark: Relaxed planning graphs have historically been defined for STRIPS tasks only. In this case, we can simplify:

- Only one effect node per operator: STRIPS does not have conditional effects.
- Because each operator has only one effect node, effect nodes are called operator nodes in relaxed planning graphs for STRIPS.
- No goal nodes: The test whether all goals are reached is done by the algorithm that evaluates the AND/OR dag.
- No formula nodes: Operator nodes are directly connected to their preconditions.
$\rightsquigarrow$ Relaxed planning graphs for STRIPS are layered digraphs and only have proposition and operator nodes.

## Computing parallel forward distances from RPGs

So far, relaxed planning graphs offer us a way to compute parallel forward distances:

Parallel

Parallel forward distances from relaxed planning graphs
def parallel-forward-distance( $\Pi^{+}$):
Let $A$ be the set of state variables of $\Pi^{+}$.
for $k \in\{0,1,2, \ldots\}$ :
$r p g:=R P G_{k}\left(\Pi^{+}\right)$
Evaluate truth values for rpg.
if goal node of $r p g$ has value 1 : return $k$
else if $k=|A|$ :
return $\infty$

## Remarks on the algorithm

- The relaxed planning graph for depth $k \geq 1$ can be built

Parallel incrementally from the one for depth $k-1$ :

- Add new layer $k$.
- Move goal subgraph from layer $k-1$ to layer $k$.
- Similarly, all truth values up to layer $k-1$ can be reused.
- Thus, overall computation with maximal depth $m$ requires time $O\left(\left\|R P G_{m}\left(\Pi^{+}\right)\right\|\right)=O\left((m+1) \cdot\left\|\Pi^{+}\right\|\right)$.
- This is not a very efficient way of computing parallel forward distances (and wouldn't be used in practice).
- However, it allows computing additional information for the relaxed planning graph nodes along the way, which can be used for heuristic estimates.

## Generic relaxed planning graph heuristics

Computing heuristics from relaxed planning graphs def generic-rpg-heuristic( $\langle A, I, O, \gamma\rangle, s)$ :

$$
\begin{aligned}
& \Pi^{+}:=\left\langle A, s, O^{+}, \gamma\right\rangle \\
& \text { for } k \in\{0,1,2, \ldots\}:
\end{aligned}
$$

$$
r p g:=R P G_{k}\left(\Pi^{+}\right)
$$

Evaluate truth values for rpg. if goal node of $r p g$ has value 1 : Annotate true nodes of $r p g$. if termination criterion is true: return heuristic value from annotations else if $k=|A|$ : return $\infty$
$\rightsquigarrow$ generic template for heuristic functions
$\rightsquigarrow$ to get concrete heuristic: fill in highlighted parts

## Concrete examples for the generic heuristic

Many planning heuristics fit the generic template:

- additive heuristic $h_{\text {add }}$ (Bonet, Loerincs \& Geffner, 1997)
- max heuristic $h_{\max }$ (Bonet \& Geffner, 1999)
- FF heuristic $h_{\text {FF }}$ (Hoffmann \& Nebel, 2001)
- cost-sharing heuristic $h_{\text {cs }}$ (Mirkis \& Domshlak, 2007)
$\square$ not covered in this course
- set-additive heuristic $h_{\text {sa }}$ (Keyder \& Geffner, 2008)

## Remarks:

- For all these heuristics, equivalent definitions that don't refer to relaxed planning graphs are possible.
- Historically, such equivalent definitions have mostly been used for $h_{\text {max }}, h_{\text {add }}$ and $h_{\text {sa }}$.
- For those heuristics, the most efficient implementations do not use relaxed planning graphs explicitly.

## Forward cost heuristics

- The simplest relaxed planning graph heuristics are forward cost heuristics.
- Examples: $h_{\text {max }}, h_{\text {add }}$
- Here, node annotations are cost values (natural numbers).
- The cost of a node estimates how expensive (in terms of required operators) it is to make this node true.

Computing annotations:

- Propagate cost values bottom-up using a combination rules for OR nodes and for AND nodes.
- At effect nodes, add 1 after applying combination rule.

Termination criterion:

- stability: terminate if cost for proposition node $a^{k}$ equals cost for $a^{k-1}$ for all true propositions a in layer $k$
Heuristic value:

Parallel

- The heuristic value is the cost of the goal node.
- Different forward cost heuristics only differ in their choice of combination rules.

Forward cost heuristics: max heuristic $h_{\max }$
Combination rule for AND nodes:
$\square \operatorname{cost}(u)=\max \left(\left\{\operatorname{cost}\left(v_{1}\right), \ldots, \operatorname{cost}\left(v_{k}\right)\right\}\right)$ (with $\max (\emptyset):=0$ )
Combination rule for OR nodes:
$\square \operatorname{cost}(u)=\min \left(\left\{\operatorname{cost}\left(v_{1}\right), \ldots, \operatorname{cost}\left(v_{k}\right)\right\}\right)$
In both cases, $\left\{v_{1}, \ldots, v_{k}\right\}$ is the set of true successors of $u$.
Intuition:

Parallel
plans
Relaxed
planning
graphs
Relaxation
heuristics
Generic template
$h_{\text {max }}$
$h_{\text {add }}$
$h_{\text {sa }}$
Incremental computation
$h_{\text {FF }}$
Comparison \& practice

- AND rule: If we have to achieve several conditions, estimate this by the most expensive cost.
- OR rule: If we have a choice how to achieve a condition, pick the cheapest possibility.

computation
$h_{\text {FF }}$
Comparison \& practice

Summary

## Remarks on $h_{\max }$

- The definition of $h_{\text {max }}$ as a forward cost heuristic is equivalent to our earlier definition in this chapter.
- Unlike the earlier definition, it generalizes to an extension where every operator has an associated non-negative cost (rather than all operators having cost 1).
- In the case without costs (and only then), it is easy to prove that the goal node has the same cost in all graphs $R P G_{k}\left(\Pi^{+}\right)$where it is true. (Namely, the cost is equal to the lowest value of $k$ for which the goal node is true.)
- We can thus terminate the computation as soon as the goal becomes true, without waiting for stability.
- The same is not true for other forward-propagating heuristics ( $h_{\text {add }}, h_{\text {cs }}, h_{\text {sa }}$ ).

## The additive heuristic

Summary

## Remarks on $h_{\text {add }}$

- It is important to test for stability in computing $h_{\text {add }}$ ! (The reason for this is that, unlike $h_{\text {max }}$, cost values of true propositions can decrease from layer to layer.)
- Stability is achieved after layer $|A|$ in the worst case.
- $h_{\text {add }}$ is safe and goal-aware.
- Unlike $h_{\text {max }}$, $h_{\text {add }}$ is a very informative heuristic in many planning domains.
- The price for this is that it is not admissible (and hence also not consistent), so not suitable for optimal planning.
- In fact, it almost always overestimates the $h^{+}$value because it does not take positive interactions into account.

## The set-additive heuristic

- We now discuss a refinement of the additive heuristic called the set-additive heuristic $h_{\text {sa }}$.
- The set-additive heuristic addresses the problem that $h_{\text {add }}$ does not take positive interactions into account.
- Like $h_{\text {max }}$ and $h_{\text {add }}, h_{\text {sa }}$ is calculated through forward propagation of node annotations.
- However, the node annotations are not cost values, but sets of operators (kind of).
- The idea is that by taking set unions instead of adding costs, operators needed only once are counted only once.

Parallel
plans
Relaxed
planning
graphs
Relaxation
heuristics
Generic template

Disclaimer: There are some quite subtle differences between the $h_{\mathrm{sa}}$ heuristic as we describe it here and the "real" heuristic of Keyder \& Geffner. We do not want to discuss this in detail, but please note that such differences exist.

- The original $h_{\text {sa }}$ heuristic as described in the literature is defined for STRIPS tasks and propagates sets of operators.
- This is fine because in relaxed STRIPS tasks, each operator need only be applied once.
- The same is not true in general: in our running example, operator $o_{1}$ must be applied twice in the relaxed plan.
- In general, it only makes sense to apply an operator again in a relaxed planning task if a previously unsatisfied effect condition has been made true.
- For this reason, we keep track of operator/effect condition pairs rather than just plain operators.

## Set-additive heuristic: fitting the template

The set-additive heuristic $h_{\text {sa }}$
Parallel
Computing annotations:

- Annotations are sets of operator/effect condition pairs, computed bottom-up.
Combination rule for AND nodes:
- $\operatorname{ann}(u)=a n n\left(v_{1}\right) \cup \cdots \cup a n n\left(v_{k}\right)($ with $\bigcup(\emptyset):=\emptyset)$

Combination rule for OR nodes:

- ann $(u)=a n n\left(v_{i}\right)$ for some $v_{i}$ minimizing $\left|a n n\left(v_{i}\right)\right|$ In case of several minimizers, use any tie-breaking rule. In both cases, $\left\{v_{1}, \ldots, v_{k}\right\}$ is the set of true successors of $u$. At effect nodes, add the corresponding operator/effect condition pair to the set after applying combination rule.

Summary

- The same remarks for stability as for $h_{\text {add }}$ apply.
- Like $h_{\text {add }}, h_{\text {sa }}$ is safe and goal-aware, but neither admissible nor consistent.
- $h_{\mathrm{sa}}$ is generally better informed than $h_{\text {add }}$, but significantly more expensive to compute.
- The $h_{\text {sa }}$ value depends on the tie-breaking rule used, so $h_{\text {sa }}$ is not well-defined without specifying the tie-breaking rule.
- The operators contained in the goal node annotation, suitably ordered, define a relaxed plan for the task.
- Operators mentioned several times in the annotation must be added as many times in the relaxed plan.

## Incremental computation of forward heuristics

One nice property of forward-propagating heuristics is that they allow incremental computation:

Summary

## Heuristic estimate $h_{\mathrm{FF}}$

- $h_{\text {sa }}$ is more expensive to compute than the other forward propagating heuristics because we must propagate sets.
- It is possible to get the same advantage over $h_{\text {add }}$ combined with efficient propagation.
- Key idea of $h_{\text {FF }}$ : perform a backward propagation that selects a sufficient subset of nodes to make the goal true (called a solution graph in AND/OR dag literature).
- The resulting heuristic is almost as informative as $h_{\text {sa }}$, yet computable as quickly as $h_{\text {add }}$.

Parallel
plans
Relaxed
planning
graphs
Relaxation
heuristics
Generic template

Note: Our presentation inverts the historical order.
The set-additive heuristic was defined after the FF heuristic (sacrificing speed for even higher informativeness).

Computing annotations:

- Annotations are Boolean values, computed top-down. A node is marked when its annotation is set to 1 and unmarked if it is set to 0 . Initially, the goal node is marked, and all other nodes are unmarked.

We say that a true AND node is justified if all its true successors are marked, and that a true OR node is justified if at least one of its true successors is marked.

## FF heuristic: fitting the template (ctd.)

## The FF heuristic $h_{\text {FF }}$ (ctd.)

Computing annotations:
Parallel

Apply these rules until all marked nodes are justified:
1 Mark all true successors of a marked unjustified AND node.
2 Mark the true successor of a marked unjustified OR node with only one true successor.
3 Mark a true successor of a marked unjustified OR node connected via an idle arc.
4 Mark any true successor of a marked unjustified OR node.
The rules are given in priority order: earlier rules are preferred if applicable.

## FF heuristic: fitting the template (ctd.)

## The FF heuristic $h_{\text {FF }}$ (ctd.)

Termination criterion:

- Always terminate at first layer where goal node is true.

Heuristic value:

- The heuristic value is the number of operator/effect condition pairs for which at least one effect node is marked.

Summary

## Remarks on $h_{\text {FF }}$

- Like $h_{\text {add }}$ and $h_{\text {sa }}, h_{\text {FF }}$ is safe and goal-aware, but neither admissible nor consistent.
- Its informativeness can be expected to be slightly worse than for $h_{\text {sa }}$, but is usually not far off.
- Unlike $h_{\text {sa }}, h_{\text {FF }}$ can be computed in linear time.
$\square$ Similar to $h_{\text {sa }}$, the operators corresponding to the marked operator/effect condition pairs define a relaxed plan.
- Similar to $h_{\text {sa }}$, the $h_{\text {FF }}$ value depends on tie-breaking when the marking rules allow several possible choices, so $h_{\text {FF }}$ is not well-defined without specifying the tie-breaking

Parallel
plans
Relaxed
planning
graphs
Relaxation
heuristics
Generic template rule.

- The implementation in FF uses additional rules of thumb to try to reduce the size of the generated relaxed plan.

Theorem (relationship between relaxation heuristics)

Let $s$ be a state of planning task $\langle A, I, O, \gamma\rangle$. Then:
$\square h_{\max }(s) \leq h^{+}(s) \leq h^{*}(s)$
$\square h_{\max }(s) \leq h^{+}(s) \leq h_{s a}(s) \leq h_{\text {add }}(s)$
$\square h_{\max }(s) \leq h^{+}(s) \leq h_{F F}(s) \leq h_{\text {add }}(s)$
$h^{*}, h_{F F}$ and $h_{s a}$ are pairwise incomparable
$\square h^{*}$ and $h_{\text {add }}$ are incomparable
Moreover, $h^{+}, h_{\text {max }}, h_{\text {add }}, h_{\text {sa }}$ and $h_{F F}$ assign $\infty$ to the same set of states.

Note: For inadmissible heuristics, dominance is in general neither desirable nor undesirable. For relaxation heuristics, the objective is usually to get as close to $h^{+}$as possible.

## Example (HSP)

HSP (Bonet \& Geffner) was one of the four top performers at the 1st International Planning Competition (IPC-1998).
Key ideas:

- hill climbing search using $h_{\text {add }}$
- on plateaus, keep going for a number of iterations, then restart
- use a closed list during exploration of plateaus

Literature: Bonet, Loerincs \& Geffner (1997), Bonet \& Geffner (2001)

## Example (FF)

FF (Hoffmann \& Nebel) won the 2nd International Planning Competition (IPC-2000).
Key ideas:

- enforced hill-climbing search using $h_{\text {FF }}$
- helpful action pruning: in each search node, only consider successors from operators that add one of the atoms marked in proposition layer 1
- goal ordering: in certain cases, FF recognizes and exploits that certain subgoals should be solved one after the other

If main search fails, FF performs greedy best-first search using $h_{\text {FF }}$ without helpful action pruning or goal ordering.

## Relaxation heuristics in practice: Fast Downward

## Example (Fast Downward)

Fast Downward (Helmert \& Richter) won the satisficing track of the 4th International Planning Competition (IPC-2004).
Key ideas:

- greedy best-first search using $h_{\text {FF }}$ and causal graph heuristic (not relaxation-based)
- search enhancements:
- multi-heuristic best-first search
- deferred evaluation of heuristic estimates

Literature: Chen, Wah \& Hsu (2006)

## Example (LAMA)

Literature: Richter, Helmert \& Westphal (2008), Richter \& Westphal (2010)

- Relaxed planning graphs are AND/OR dags. They encode
which propositions can be made true in $\Pi^{+}$and how.
- Closely related to forward sets and forward plan steps, based on the notion of parallel relaxed plans.
- They can be constructed and evaluated efficiently, in time $O\left((m+1)\left\|\Pi^{+}\right\|\right)$for planning task $\Pi$ and depth $m$.
- By annotating RPG nodes with appropriate information, we can compute many useful heuristics.
- Examples: max heuristic $h_{\max }$, additive heuristic $h_{\text {add }}$, set-additive heuristic $h_{\text {sa }}$ and FF heuristic $h_{\text {FF }}$
- Of these, only $h_{\max }$ admissible (but not very accurate).
- The others are much more informative. The set-additive heuristic is the most sophisticated one.
$\square$ The FF heuristic is often similarly informative. It offers a good trade-off between accuracy and computation time.
