SAT

Definition (SAT)

Given a propositional formula \mathcal{F} , decide whether \mathcal{F} has a satisfying valuation.

Definition (CNF-SAT)

Given a propositional formula \mathcal{F} in conjunctive normal form, decide whether \mathcal{F} has a satisfying valuation.

A valuation is an assignment of decision variables to $\{\top, \perp\}$.

CNF:

$$\mathcal{F} = \bigwedge_{C \in \mathcal{C}} \bigvee_{l \in C} l$$

(\mathcal{C} is the set of clauses; C is a clause, a set of literals.)

- SAT solvers are programs that determine whether a satisfying valuation exists and if so output it.
- A **lot** of research in recent years (annual competitions since 2002).
- Usable OSES have `minisat` in their package manager.
- Standardised input format DIMACS:

`p cnf 5 3` CNF with 5 vars and 3 clauses:
`1 -5 4 0` $(v_1 \vee \neg v_5 \vee v_4) \wedge$
`-1 5 3 4 0` $(\neg v_1 \vee v_5 \vee v_3 \vee v_4) \wedge$
`-3 -4 0` $(\neg v_3 \vee \neg v_4)$

Definition

Given a graph $G = (V, E)$ and a number k .
 Is there an assignment of k colours to the vertices of G , such that all adjacent vertices have different colours?

- SAT Modelling
- Problem Solving
- SAT
- SAT Solvers
- Modelling Example
- Theoretical Background
- Sequential Classical Planning in SAT
- Invariants
- \forall -step
- \exists -step

Variables for choosing the colour of each node

$colour_v^i$ where $v \in V$ and $i \in \{1, \dots, k\}$

If a node has a colour, all adjacent nodes have a different colour

$$\begin{aligned}
 colour_v^i &\rightarrow \neg colour_w^i & \forall (v, w) \in E \\
 \neg colour_v^i &\vee \neg colour_w^i & \forall (v, w) \in E
 \end{aligned}$$

Every node has a colour

$$\bigvee_{i=1}^k colour_v^i \quad \forall v \in V$$

Every node has at most one colour

$$\bigwedge_{i=1}^k \left[colour_v^i \rightarrow \bigwedge_{j=1, j \neq i}^k \neg colour_v^j \right] \quad \forall v \in V$$

Definition (PLANEx)

Given a planning problem \mathcal{P} .
Is there a solution π of \mathcal{P} .

Theorem (Bylander'94)

PLANEx is PSPACE-complete.

Theorem (Bylander'94)

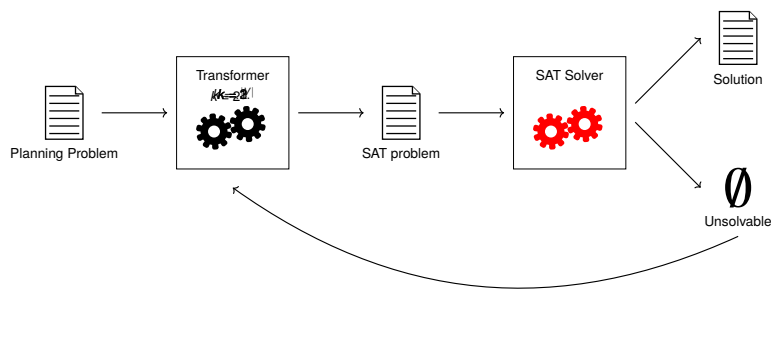

PLANEx with bounded plan length k is PSPACE-complete.

PSPACE with NP calculus?

- SAT Modelling

- Invariants
- \forall -step
- \exists -step

- Bounded plan length assumes binary encoding of k .
- What if we assume k in unary encoding?
- PLANEx “becomes” NP-“complete”.
- For full PLANEx: how to choose the plan length?
 - Theoretical limit: $2^{|V|}$.
 - Practical limit: usually smaller (sometimes polynomially bounded).
- Start with a small k and increase until a solution is found.

Classical Planning via SAT

[Kautz&Selman'92]

A plan is just a sequence of state transitions.

- “Mechanics” is identical in all timesteps.
- Just model one timestep and copy'n'paste.
- Edge constraints!

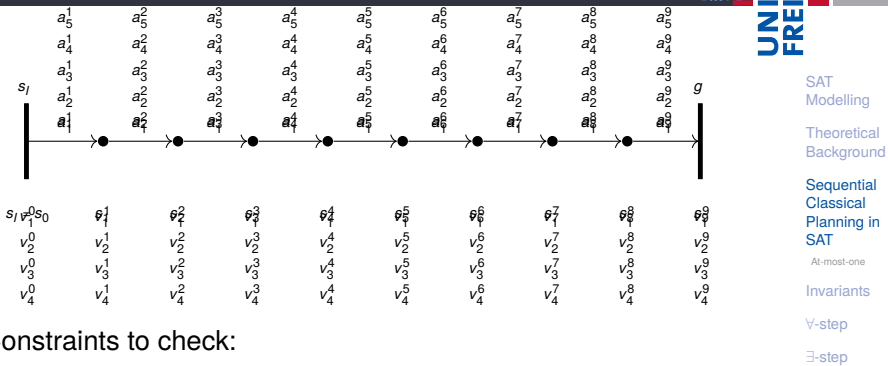

Decision Variables

We only need two types of decision variables!

- 1 a_i^t – Action i is executed at time t .
- 2 v_i^t – State variable i is true at time t .

Overall Formula

Constraints to check:

- Correctly applying actions at each time step (τ).
- s_I and g must be respected.

$$\mathcal{F} = \bigwedge_{t=0}^{k-1} \tau(t) \wedge \bigwedge_{v_i \in s_I} v_i^0 \wedge \bigwedge_{v_i \in V \setminus s_I} \neg v_i^0 \wedge \bigwedge_{v_i \in g} v_i^k \quad \text{here: } k = 9$$

Classical Planning via SAT

Constraints to check by $\tau(t)$:

- F_1 Preconditions must hold (in s).
- F_2 Effects must occur (in s').
- F_3 Unaffected state variables stay unchanged.
- F_4 At most one action per timestep.
- F_5 At least one action per timestep. Necessary? **No**.

- Preconditions must hold:

$$F_1 = \bigwedge_{a \in A} a^{t+1} \rightarrow \bigwedge_{v \in pre(a)} v^t$$

- Effects must occur:

$$F_2 = \left[\bigwedge_{a \in A} a^{t+1} \rightarrow \bigwedge_{v \in add(a)} v^{t+1} \right] \wedge \left[\bigwedge_{a \in A} a^{t+1} \rightarrow \bigwedge_{v \in del(a)} \neg v^{t+1} \right]$$

SAT Modelling
Theoretical Background
Sequential Classical Planning in SAT
At-most-one
Invariants
Y-step
Z-step

- Variables not affected by the executed action must stay the same.

→ Frame Problem!

$$F_3 = \bigwedge_{v \in V} \left[(\neg v^t \wedge v^{t+1}) \rightarrow \bigvee_{a \in A \text{ with } v \in add(a)} a^{t+1} \right] \wedge \bigwedge_{v \in V} \left[(v^t \wedge \neg v^{t+1}) \rightarrow \bigvee_{a \in A \text{ with } v \in del(a)} a^{t+1} \right]$$

- Only one action at a time:

$$F_4 = \text{at-most-one}(\{a^t \mid a \in A\})$$

Classical Planning via SAT

There are **a lot** of improvements to this formula.

- Invariants.
- \forall -step semantics.
- \exists -step semantics.

SAT Modelling
Theoretical Background
Sequential Classical Planning in SAT
At-most-one
Invariants
 \forall -step
 \exists -step

Invariants

What are Invariants?

Is there **anything** we know about states in a planning problem?

Definition (Invariant)

An invariant \mathcal{I} is a formula over the state variables such that for all states s reachable from s_1 it holds $s \models \mathcal{I}$.

What are Invariants?

Predicates:

- $on(x, y)$ – x lies directly on y .
- $free(x)$ – x has no block above it.

Actions:

- $pickup(x)$ – pick up x , if it is free.
- $putdown(x, y)$ – put x on y , if y is free (*table* is always free).

Are the following formulae invariants?

- 1 $\forall b \in Block : (\exists b' \in Block : on(b', b)) \vee free(b)$ — **Yes.**
- 2 $\forall b \in Block : on(b, table)$ — **No.**
- 3 $\forall b, b' \in Block : \neg on(b', b) \vee \neg on(b, b')$ — **Yes.**

Invariants are Difficult

How hard is verifying an invariant?
As hard as planning.
Also there are too many invariants.

- Compute an approximation of all invariants of a fixed form.
- Restrict to binary-or invariants:

$$l_1 \vee l_2$$

Note: Here we consider some action $a = (pre, add, del)$ and denote with $eff = add(a) \cup \{\neg v \mid v \in del(a)\}$ its effects (as a literal set).

$$\neg V = \{\neg v \mid v \in V\} \quad (\ell \in V^{-V} \text{ denotes a literal.})$$

$U_{\langle pre, eff \rangle}(\mathcal{I})$ gives all properties (positive or negative state variables) that hold after the execution of an action $a = \langle pre, eff \rangle$

$$\equiv (\{\neg v \mid v \in add\} \cup del)$$

$$U_{\langle pre, eff \rangle}(\mathcal{I}) = (\{\ell \in V \cup \neg V \mid \mathcal{I} \cup pre \models \ell\} \setminus \{\neg \ell \mid \ell \in eff\}) \cup eff$$

$F_{\langle pre, eff \rangle}(\mathcal{I})$ is a filter for invariants, returning those that hold after the execution of an action $a = \langle pre, eff \rangle$

$$F_{\langle pre, eff \rangle}(\mathcal{I}) = \begin{cases} \mathcal{I} & \text{if } \mathcal{I} \cup pre \models \perp \text{ and otherwise:} \\ \{\ell_1 \vee \ell_2 \in \mathcal{I} \mid (\neg \ell_1 \notin eff \text{ or } \ell_2 \in U_{\langle pre, eff \rangle}(\mathcal{I})) \text{ and} \\ \quad (\neg \ell_2 \notin eff \text{ or } \ell_1 \in U_{\langle pre, eff \rangle}(\mathcal{I}))\} \end{cases}$$

- SAT Modelling
- Theoretical Background
- Sequential Classical Planning in SAT
- Invariants**
- \forall -step
- \exists -step

Call $R_A(\mathcal{I}) := F_{a_1}(F_{a_2}(\dots F_{a_n}(\mathcal{I}) \dots))$ with initial invariant $I_{init} = \{v \vee \ell \mid v \in s_I, \ell \in V \cup \neg V\} \cup \{\neg v \vee \ell \mid v \notin s_I, \ell \in V \cup \neg V\}$ and arbitrary linearization of action set A, a_1, \dots, a_n , until \mathcal{I} does not change anymore.

R stands for "reduce invariant set".

Linear Plans are Bad!

Consider the following (single) planning problem:

drive(A,B), load(B), drive(B,C), unload(C), drive(F,D), load(D), drive(D,E), unload(E)

drive(A,B) load(B) drive(B,C) unload(C)
drive(F,D) load(D) drive(D,E) unload(E)

- SAT Modelling
- Theoretical Background
- Sequential Classical Planning in SAT
- Invariants
- \forall -step
- \exists -step

\forall -step [Kautz&Selman'96]

Allow parallel execution of actions.
But when?

- Let \mathcal{A} be some set of actions.
- Parallel execution of \mathcal{A} is safe, if all (\forall) linearisations of \mathcal{A} are executable.
- Necessary conditions:
 - All actions are executable in the previous state as all could be the first.
 - No action can have a delete-effect that is a precondition of another action, i.e., $\forall a_1 \neq a_2 \in \mathcal{A} : del(a_1) \cap prec(a_2) = \emptyset$, as a_1 can occur before a_2 .
- Sufficient conditions: Necessary conditions are already sufficient.

- SAT Modelling
- Theoretical Background
- Sequential Classical Planning in SAT
- Invariants
- \forall -step
- \exists -step

Encoding \forall -step

Remove the at-most-one constraints. Two options:

$$a_1^t \rightarrow \neg a_2^t \quad \forall a_1, a_2 \in A \text{ with } del(a_1) \cap prec(a_2) \neq \emptyset$$

→ quadratic effort.

$$a^t \rightarrow del_v^t \quad \forall a \in A, v \in del(a)$$

$$del_v^t \rightarrow \neg a^t \quad \forall a \in A, v \in prec(a)$$

→ linear effort.

Further implications?

The resulting state must always be the same!

Thus we forbid two actions a_1, a_2 with $del(a_1) \cap add(a_2) \neq \emptyset$ to be executed in parallel.

(Otherwise the resulting state would not be unique.)

- SAT Modelling
- Theoretical Background
- Sequential Classical Planning in SAT
- Invariants
- \forall -step
- \exists -step

\exists -step

Parallel Plans are (Still) Bad!

(Re-)Consider the following (single) planning problem:

drive(A, B) load(B) drive(B, C) unload(C)
 drive(F, D) load(D) drive(D, E) unload(E)

drive(A, B) load(B) unload(C)
 drive(B, C)
 drive(F, D) load(D) unload(E)
 drive(D, E)

- SAT Modelling
- Theoretical Background
- Sequential Classical Planning in SAT
- Invariants
- \forall -step
- \exists -step

What Kind of Parallelism do we Look for?

- Absolutely safe parallelism.
 - All linearisations will always be executable and lead to the same state.
 - \forall -step.
- (Sometimes) Safe parallelism.
 - At least one linearisation is executable and all executable linearisations lead to the same state.
 - \exists -step.

- SAT Modelling
- Theoretical Background
- Sequential Classical Planning in SAT
- Invariants
- \forall -step
- \exists -step

\exists -step Parallelism

- Given a set of actions \mathcal{A} . We call them \exists -step executable if a linearisation exists that is executable and all executable linearisations lead to the same state.
- How difficult to determine? First part is NP-complete.
- How to encode?
- Results in the Kautz&Selman encoding ...

- SAT Modelling
- Theoretical Background
- Sequential Classical Planning in SAT
- Invariants
- \forall -step
- \exists -step

Disabling Graph [Rintanen, Heljanko, Niemelä'06]

- Approximate \exists -step semantics.
- Analyse dependency between actions.
- Similar to \forall -step:
 - If $del(a) \cap pre(a') \neq \emptyset$, execute a' before a .
 - Ignore if $\mathcal{S} \cup pre(a) \cup pre(a')$ is inconsistent.

- SAT Modelling
- Theoretical Background
- Sequential Classical Planning in SAT
- Invariants
- \forall -step
- \exists -step

- Disabling Graph: $a \rightarrow b$ iff after executing a it may not be possible to execute b .
- We can safely execute actions in reverse topological order.
- DG may not be acyclic.
- Guess an order in every SCC and order SCCs in reverse topological order.
- If executed in parallel, we will always execute actions in **this** order.

a_5, a_4, a_2, a_3, a_1
 $(a_5), (a_2, a_3, a_4), (a_1)$

SAT Modelling
 Theoretical Background
 Sequential Classical Planning in SAT
 Invariants
 ∀-step
 ∃-step

What do we have to assert inside the propositional formula?

- Parallel actions must result in a consistent state. ✓
- Parallel actions must be executable.

- Actions must be applicable in the previous state.
- Reverse topological order of DG ensures that later actions are still applicable.
- In SCCs there might be edges opposite to the chosen order.
- SCC can be treated separately.
- If a_2 is executed, then a_4 must not.
- Enforced via *chaines*.

a_5, a_2, a_3, a_4, a_1
 $(a_5), (a_2, a_3, a_4), (a_1)$

SAT Modelling
 Theoretical Background
 Sequential Classical Planning in SAT
 Invariants
 ∀-step
 ∃-step

We are given an SCC and an ordering of its vertices.

$\pi = (a_5, a_4, a_3, a_2, a_1)$

- We want choose an acyclic subsequence of π .
- Approx.: Do not choose both ends of a forward edge.
- Iterate over causes of these edges: $v \in del(a_1) \cap pre(a_2)$
 - E_v – subsequence of π with $v \in del(a)$ (Erasing)
 - R_v – subsequence of π with $v \in pre(a)$ (Requiring)

$$\bigwedge \{ \pi^i \rightarrow \pi^j \mid i < j, \pi^i \in E_v, \pi^j \in R_v, \{a_{i+1}, \dots, a_{j-1}\} \cap R_v = \emptyset \} \cup$$

$$\{ \pi^i \rightarrow \pi^j \mid i < j, \{ \pi^i, \pi^j \} \in R_v, \{a_{i+1}, \dots, a_{j-1}\} \cap R_v = \emptyset \} \cup$$

$$\{ \pi^i \rightarrow \neg \pi^i \mid \pi^i \in R_v \}$$

 Sequential Classical Planning in SAT
 Invariants
 ∀-step
 ∃-step

Improvements for classical planning:

- Extension to conditional effects [Rintanen,Heljanko,Niemelä'06].
- Relaxed ∃-step [Wehrle&Rintanen'07].
- Parallel SAT search [Rintanen'04] [Rintanen,Heljanko,Niemelä'06].
- Specialised heuristics for SAT solvers [Rintanen'10a] [Rintanen'10b].
- Improved memory management [Rintanen'12].
- Incremental SAT-solving [Gocht&Balyo'17].

Extensions to non-classical planning:

- LTL [Mattmüller&Rintanen'07] [Behnke&Biundo'18].
- Partial Observability [Pandey&Rintanen'18].
- Temporal Planning [Rintanen'17].
- HTN Planning [Behnke,Höller,Biundo'17'18].
