

Constraint Satisfaction Problems

Enforcing Consistency

Malte Helmert and Stefan Wöfl

Albert-Ludwigs-Universität Freiburg

April 24, 2007

Enforcing Consistency

- The more explicit and tight constraint networks are, the more restricted is the search space of partial solutions.
- **Idea:** infer at least a limited number of new constraints (by methods called **local consistency-enforcing**, **bounded consistency inference**, **constraint propagation**).
- Consistency-enforcing algorithms aim at *assisting search*:
How can we extend a given partial solution of a small subnetwork to a partial solution of a larger subnetwork?

i-Consistency

AC Extensions

Convention

In what follows we will always assume that the variables of a constraint network appear in some order. Then we can write constraint networks in the form:

$$\mathcal{C} = \langle V, D, C \rangle,$$

where D_i is the (possibly empty) domain of variable v_i , and constraints in the form R_{ijk} , where $\{v_i, v_j, v_k\}$ is the scope of the relation.

Further, we assume that C does not contain unary constraints, i. e., constraints in C are always relations with arity $n > 1$.

This is possible, since we can define:

$$D_i := \text{dom}(v_i) \cap R_{v_i}$$

and then delete R_{v_i} from the original network.

D_i will be referred to as **domains**, **unary constraint**, or **domain constraint**.

Arc
Consistency

Path
Consistency

i-Consistency

AC Extensions

Arc Consistency

Let $\mathcal{C} = \langle V, D, C \rangle$ be a constraint network.

Definition

- (a) A variable v_i is **arc-consistent** relative to variable v_j if for every value $a_i \in D_i$ there exists an $a_j \in D_j$ with $(a_i, a_j) \in R_{ij}$ (in case that R_{ij} exists in C).
- (b) An “arc constraint” R_{ij} is **arc-consistent** if v_i is arc-consistent relative to v_j and v_j is arc-consistent relative to v_i .
- (c) A network \mathcal{C} is **arc-consistent** if all its arc constraints are arc-consistent.

Lemma

Checking whether a network $\mathcal{C} = \langle V, D, C \rangle$ is arc-consistent requires $e \cdot k^2$ operations (where e is the number of its binary constraints and k is an upper bound of its domain sizes).

Constraint
Satisfaction
Problems

Arc
Consistency

Path
Consistency

i -Consistency

AC Extensions

Example

Consider a constraint network with two variables v_1 and v_2 , domains $D_1 = D_2 = \{1, 2, 3\}$, and the binary constraint expressed by $v_1 < v_2$.

Figure: A network that is not arc-consistent

Revising a Single Domains

Revise (v_i, v_j):

Input: a network with two variables v_i, v_j ,
domains D_i and D_j , and constraint R_{ij}

Output: a network with refined D_i such that v_i
is arc-consistent relative to v_j

for each $a_i \in D_i$

if there is no $a_j \in D_j$ with $(a_i, a_j) \in R_{ij}$

then delete a_i from D_i

endif

endfor

This is equivalent to applying:

$$D_i \leftarrow D_i \cap \pi_i(R_{ij} \bowtie D_j)$$

Enforcing Arc Consistency: AC-1

Lemma

Let \mathcal{C} be a constraint network with n variables, each with a domain of size $\leq k$, and e binary constraints.

Applying AC-1 on the network runs in time $\mathcal{O}(e \cdot n \cdot k^3)$.

Proof.

One cycle through all binary constraints takes $\mathcal{O}(e \cdot k^2)$. In the worst case, one cycle just removes one value from one domain. Moreover, there are at most $n \cdot k$ values. This results in an upper bound of $\mathcal{O}(e \cdot n \cdot k^3)$. □

Note: If the input network is already arc-consistent, then AC-1 runs in time $\mathcal{O}(e \cdot k^2)$.

AC Extensions

Example: AC-1

Consider a constraint network with three variables v_1 , v_2 , and v_3 , domains $D_1 = D_2 = \{1, 2, 3\}$, and the binary constraints expressed by $v_1 < v_2$ and $v_2 < v_3$.

Example: AC-1

Consider a constraint network with three variables v_1 , v_2 , and v_3 , domains $D_1 = D_2 = \{1, 2, 3\}$, and the binary constraints expressed by $v_1 < v_2$ and $v_2 < v_3$.

Example: AC-1

Consider a constraint network with three variables v_1 , v_2 , and v_3 , domains $D_1 = D_2 = \{1, 2, 3\}$, and the binary constraints expressed by $v_1 < v_2$ and $v_2 < v_3$.

Example: AC-1

Consider a constraint network with three variables v_1 , v_2 , and v_3 , domains $D_1 = D_2 = \{1, 2, 3\}$, and the binary constraints expressed by $v_1 < v_2$ and $v_2 < v_3$.

Example: AC-1

Consider a constraint network with three variables v_1 , v_2 , and v_3 , domains $D_1 = D_2 = \{1, 2, 3\}$, and the binary constraints expressed by $v_1 < v_2$ and $v_2 < v_3$.

Example: AC-1

Consider a constraint network with three variables v_1 , v_2 , and v_3 , domains $D_1 = D_2 = \{1, 2, 3\}$, and the binary constraints expressed by $v_1 < v_2$ and $v_2 < v_3$.

Example: AC-1

Consider a constraint network with three variables v_1 , v_2 , and v_3 , domains $D_1 = D_2 = \{1, 2, 3\}$, and the binary constraints expressed by $v_1 < v_2$ and $v_2 < v_3$.

Example: AC-1

Consider a constraint network with three variables v_1 , v_2 , and v_3 , domains $D_1 = D_2 = \{1, 2, 3\}$, and the binary constraints expressed by $v_1 < v_2$ and $v_2 < v_3$.

Example: AC-1

Consider a constraint network with three variables v_1 , v_2 , and v_3 , domains $D_1 = D_2 = \{1, 2, 3\}$, and the binary constraints expressed by $v_1 < v_2$ and $v_2 < v_3$.

Note: Enforcing arc consistency may already be sufficient to show that a constraint network is inconsistent. For example, add the constraint $v_3 < v_1$ to the network just considered.

Enforcing Arc Consistency: AC-3

Idea: no need to process all constraints if only a few domains have changed. Hence operate on a queue of constraints that need to be processed.

AC-3(\mathcal{C}):

Input: a constraint network $\mathcal{C} = \langle V, D, C \rangle$

Output: an equivalent, but arc-consistent network \mathcal{C}'

for each pair v_i, v_j that occurs in a constraint R_{ij}

$queue \leftarrow queue \cup \{(v_i, v_j), (v_j, v_i)\}$

endfor

while $queue$ is not empty

select and delete (v_i, v_j) from $queue$

Revise(v_i, v_j)

if Revise(v_i, v_j) changes D_i

then $queue \leftarrow queue \cup \{(v_k, v_i) : k \neq i, k \neq j\}$

endif

Enforcing Arc Consistency: AC-3

Lemma

Let \mathcal{C} be a constraint network with n variables, each with a domain of size $\leq k$, and e binary constraints.

Applying AC-3 on the network runs in time $\mathcal{O}(e \cdot k^3)$.

Proof.

Consider a single constraint. Each time, when it is reintroduced into the queue, the domain of one of its variables must have been changed. Since there are at most $2 \cdot k$ values, AC-3 processes each constraint at most $2 \cdot k$ times. Because we have e constraints and processing of each is in time $\mathcal{O}(k^2)$, we obtain $\mathcal{O}(e \cdot k^3)$. □

Note: If the input network is arc-consistent, then AC-3 runs in time $\mathcal{O}(e \cdot k^2)$.

Arc
Consistency

Path
Consistency

i-Consistency

AC Extensions

Enforcing Arc Consistency: AC-4

- To verify that a network is arc-consistent needs $e \cdot k^2$ operations.
- The following algorithm AC-4 achieves optimal performance, ...
- at the cost of “best case performance”, which is $\Omega(e \cdot k^2)$.

Idea:

- Associate to each value a_i in the domain of variable v_i the amount of **support** from variable v_j (i. e., the number of values in D_j that are consistent with a_i);
- Delete a value a_i if it has no support from any other variable

Details:

- *List*: currently unsupported variable-value pairs;
- *counter*(x_i, a_i, x_j): support for a_i from x_j ;
- S_{x_j, a_j} : array pointing to all values in other variables supported by (x_j, a_j) ;
- *M*: list of removed values.

endwhile

Constraint
Satisfaction
Problems

S. Wöfl,
M. Helmert

Arc
Consistency

Path
Consistency

i-Consistency

AC Extensions

Example

Consider the same network as for AC-3.

The initialization steps yield:

$$S_{v_3,2} = \{(v_1, 2), (v_1, 4), (v_2, 2)\} \quad S_{v_3,5} = \{(v_2, 5)\}$$

$$S_{v_2,2} = \{(v_3, 2)\} \quad S_{v_2,5} = \{(v_3, 5)\}$$

$$S_{v_1,2} = \{(v_3, 2)\} \quad S_{v_1,4} = \{(v_3, 2)\}$$

Furthermore:

$$\text{counter}(v_3, 2, v_1) = 2 \quad \text{and} \quad \text{counter}(v_3, 5, v_1) = 0.$$

All other counters are 1 (note: we only need consider counters between connected variables).

$$List = \{(v_3, 5)\} \quad \text{and} \quad M = \emptyset.$$

When $(v_3, 5)$ is removed from $List$ and added to M , we obtain $\text{counter}(v_2, 5, v_3) = 0$ and add $(v_2, 5)$ to $List$. Then $(v_2, 5)$ is removed from $List$ and added to M . $(v_2, 5)$ is only supported by $(v_3, 5)$, but that pair is already in M , and we are done.

Beyond Arc Consistency

- Sometimes “enforcing arc consistency” is sufficient for detecting inconsistent (unsolvable) networks; but . . .
- enforcing arc consistency is not **complete** for deciding consistency of networks; because . . .
- inferences rely only on domain constraints and single binary constraints defined on the domains.

⇒ We consider further concepts of **local consistency**

M. Helmert

Arc
Consistency

Path
Consistency

i-Consistency

AC Extensions

Path Consistency

Definition

- (a) A binary constraint R_{ij} for variables v_i, v_j is **path-consistent** relative to a third variable v_k if for every pair $(a_i, a_j) \in R_{ij}$, there exists an $a_k \in D_k$ such that $(a_i, a_k) \in R_{ik}$ and $(a_k, a_j) \in R_{kj}$.
- (b) A pair of distinct variables v_i, v_j is **path-consistent** relative to variable v_k if any instantiation a of $\{v_i, v_j\}$ with $(a(v_i), a(v_j)) \in R_{ij}$ can be extended to an instantiation a' of $\{v_i, v_j, v_k\}$ such that $(a'(v_i), a'(v_k)) \in R_{ik}$ and $(a'(v_k), a'(v_j)) \in R_{kj}$ (“extended” means: $a = a'|_{\{v_i, v_j\}}$).
- (c) A set of distinct variables $\{v_i, v_j, v_k\}$ is **path-consistent** if any pair of these variables is path-consistent relative to the omitted third variable.
- (d) A constraint network is **path-consistent** if all its three-element subsets of variables are path-consistent.

An Example

Figure: This network is arc-consistent, but not path-consistent.

Revising a Path

Revise-3($\{v_i, v_j\}, v_k$):

Input: a binary network $\langle V, D, C \rangle$ with variables v_i, v_j, v_k

Output: a revised constraint R_{ij} path-consistent with v_k

```
for each pair  $(a_i, a_j) \in R_{ij}$ 
    if there is no  $a_k \in D_k$  such that  $(a_i, a_k) \in R_{ik}$ 
        and  $(a_j, a_k) \in R_{jk}$ 
        then delete  $(a_i, a_j)$  from  $R_{ij}$ 
    endif
endfor
```

Enforcing Path Consistency: Complexity of PC-1

Proof (worst case).

In each iteration of the outer loop in PC-1, only one value pair might be deleted from one of the constraints. Hence the number of iterations may be as large as $\mathcal{O}(n^2 \cdot t)$.

Processing a specific triple of constraints (there are $\mathcal{O}(n^3)$ many such triples) costs $\mathcal{O}(t \cdot k)$.

Hence each iteration costs $\mathcal{O}(n^3 \cdot t \cdot k)$. □

Proof (best case).

In the best case, the network is already path-consistent and only one iteration through the outer loop is needed. There are $\Omega(n^3)$ calls to Revise-3, each requiring time $\Omega(t)$ in the best case. □

Enforcing Path Consistency: Soundness of PC-2

Lemma

When applied to a constraint network \mathcal{C} , the PC-2 algorithm computes a path-consistent constraint network which is equivalent to \mathcal{C} .

Proof.

Equivalence follows directly from the properties of Revise-3. To see that the remaining constraint network is path-consistent, verify the following invariant:

*Before and after each iteration of the **while**-loop, for each pair v_i, v_j which is not path-consistent relative to v_k , one of the triples (i, k, j) and (j, k, i) is contained in the queue.*

Enforcing Path Consistency: Complexity of PC-2

Proof (worst case).

There are initially $\mathcal{O}(n^3)$ elements in the queue. Whenever some constraint R_{ij} is reduced, which can happen at most $\mathcal{O}(n^2 \cdot t)$ many times, $\mathcal{O}(n)$ elements are added to the queue. Thus, the total number of elements added to the queue is bounded by $\mathcal{O}(n^3 \cdot t)$.

Each iteration of the **while** loop removes an element from the queue, so there are at most $\mathcal{O}(n^3 \cdot t)$ iterations and hence at most $\mathcal{O}(n^3 \cdot t)$ calls to Revise-3, each requiring time $\mathcal{O}(t \cdot k)$, for a total runtime bound of $\mathcal{O}(n^3 \cdot t^2 \cdot k)$. □

Proof (best case).

Similar to PC-1. □

Higher Levels of i -Consistency

The local consistency notions presented so far can be roughly summarized as follows:

- **Arc consistency:** Every consistent assignment to a single variable can be consistently extended to any second variable.
- **Path consistency:** Every consistent assignment to two variables can be consistently extended to any third variable.

(Side remark: This is a bit of an oversimplification because we ignored k -ary constraints with $k \geq 3$ so far. More on this later.)

It is easy to see that the general idea of local consistency can be readily extended to larger variable sets.

i -Consistency

Let $\mathcal{C} = \langle V, D, C \rangle$ be a constraint network.

Definition

- (a) A relation $R_S \in C$ with scope S of size $i - 1$ is **i -consistent** relative to variable $v_i \notin S$ if for every tuple $t \in R_S$, there exists an $a \in D_i$ such that (t, a) is consistent.
- (b) A constraint network is **i -consistent** if any consistent instantiation of $i - 1$ (distinct) variables v_1, \dots, v_{i-1} of the network can be extended to a *consistent* instantiation of the variables v_1, \dots, v_i , where v_i is any variable in V distinct from v_1, \dots, v_{i-1} .

Global Consistency

Constraint
Satisfaction
Problems

S. Wöfl,

i-Consistency: Complexity

Lemma

Let \mathcal{C} be a constraint network with n variables, each with a domain of size $\leq k$. When applied to \mathcal{C} , the “Enforce i -Consistency” algorithm runs in time $\mathcal{O}(2^i \cdot (n \cdot k)^{2i-1})$.

Proof.

Each call to Revise- i requires time $\mathcal{O}((2 \cdot k)^i)$. In each iteration of the outer loop, $\mathcal{O}(n^i)$ combinations of S and v_i need to be processed. If only one tuple is removed from one constraint in each iteration up to the final one, the outer loop may need to iterate $\mathcal{O}(n^{i-1} \cdot k^{i-1})$ times.

This leads to an overall runtime of $\mathcal{O}(2^i \cdot (n \cdot k)^{2i-1})$. □

Note: Improvements similar to AC-4 and PC-4 exist and achieve a worst-case runtime of $\mathcal{O}(n^i \cdot k^i)$.

Extensions of Arc Consistency

- General i -consistency is powerful, but expensive to enforce.
- Usually, arc consistency and path consistency offer a good compromise between pruning power and computational overhead.
- However, they are of limited usefulness for constraints on more than two variables.

Example

Consider a constraint network with three integer variables $v_1, v_2, v_3 \geq 0$ and the constraints $v_3 \geq 13$ and $v_1 + v_2 + v_3 \leq 15$.

We should be able to infer $v_1 \leq 2$ and $v_2 \leq 2$, but regular arc consistency is not enough!

⇒ Consider generalizations of arc consistency to non-binary constraints.

↪ Consider generalizations of arc consistency to non-binary constraints.

Generalized Arc Consistency

Let $\mathcal{C} = \langle V, D, C \rangle$ be a constraint network.

Definition

- (a) A variable v_i is **(generalized) arc-consistent** relative to a constraint $R \in C$ whose scope contains v_i if for every value $a_i \in D_i$ there exists a tuple $\bar{a} \in R$ with $\bar{a}_i = a_i$.
- (b) A constraint $R \in C$ is **(generalized) arc-consistent** iff all variables in its scope are generalized arc-consistent relative to R .
- (c) A network \mathcal{C} is **(generalized) arc-consistent** if all its constraints are generalized arc-consistent.

Generalized Arc Consistency: Update Rule

Constraint
Satisfaction
Problems

S. Wöfl,
M. Helmert

To enforce generalized arc consistency, repeatedly apply

$$D_i \leftarrow D_i \cap \pi_i(R_S \bowtie D_{S \setminus \{v_i\}})$$

Note how this generalizes the usual arc consistency update rule:

$$D_i \leftarrow D_i \cap \pi_i(R_{ij} \bowtie D_j)$$

Arc
Consistency

Path
Consistency

i-Consistency

AC Extensions

Alternatives to Generalized Arc Consistency

- Like arc consistency, generalized arc consistency propagates constraints by considering **a single constraint** at a time.
- In particular, it considers how assignments to **each individual variable** are restricted by the values allowed for the other variables participating in the constraint.
- Alternatively, we can consider how each individual variable restricts the values allowed **for the other variables** participating in the constraint:

$$R_{S \setminus \{v_i\}} \leftarrow R_{S \setminus \{v_i\}} \cap \pi_{S \setminus \{v_i\}}(R_S \bowtie D_i)$$

(**relational arc consistency**)

- Note that in the case of binary constraints, these two cases are the same, so both approaches are natural generalizations of (binary) arc consistency.

Generalizations of Arc Consistency: Comparison

$$\text{AC: } D_i \leftarrow D_i \cap \pi_i(R_{ij} \bowtie D_j)$$

$$\text{generalized AC: } D_i \leftarrow D_i \cap \pi_i(R_S \bowtie D_{S \setminus \{v_i\}})$$

$$\text{relational AC: } R_{S \setminus \{v_i\}} \leftarrow R_{S \setminus \{v_i\}} \cap \pi_{S \setminus \{v_i\}}(R_S \bowtie D_i)$$

Example

Consider a constraint network with three integer variables $v_1, v_2, v_3 \geq 0$ and the constraints $v_3 \geq 13$ and $v_1 + v_2 + v_3 \leq 15$.

- Generalized AC infers $v_1 \leq 2, v_2 \leq 2$.
- Relational AC infers $v_1 + v_2 \leq 2$.

$$\text{relational AC: } R_{S \setminus \{v_i\}} \leftarrow R_{S \setminus \{v_i\}} \cap \pi_{S \setminus \{v_i\}}(R_S \bowtie D_i)$$

Example

Consider a constraint network with three integer variables $v_1, v_2, v_3 \geq 0$ and the constraints $v_3 \geq 13$ and $v_1 + v_2 + v_3 \leq 15$.

- Generalized AC infers $v_1 \leq 2, v_2 \leq 2$.
- Relational AC infers $v_1 + v_2 \leq 2$.
