

5 AVL trees: deletion

Summer Term 2011

Jan-Georg Smaus

Albert-Ludwigs-Universität Freiburg

Reminder: Definition of AVL trees

Definition: A binary search tree is called **AVL tree** or **height-balanced tree**, if for each node v the **height of the right subtree** $h(T_r)$ of v and the **height of the left subtree** $h(T_l)$ of v differ by at most 1.

Balance factor:

$$bal(v) = h(T_r) - h(T_l) \in \{-1, 0, +1\}$$

31.05.2011 Theory 1 - AVL trees: deletion 2

Deletion from an AVL tree

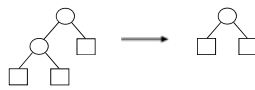

- We proceed similarly to standard search trees:
 - Search for the key to be deleted.
 - If the key is not contained, we are done.
 - Otherwise we distinguish three cases:
 - The node to be deleted has **two leaves** as its children.
 - The node to be deleted has **one internal node and one leaf as its children**.
 - The node to be deleted has **two internal nodes** as its children.
- After deleting a node the AVL property may be violated (similar to insertion). This must be fixed appropriately.

31.05.2011 Theory 1 - AVL trees: deletion 3

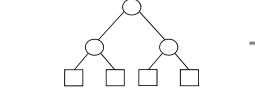

Node has only leaves as its children

Subcase of a one-node tree

2 subcases: sibling has height 0. May need readjustment.

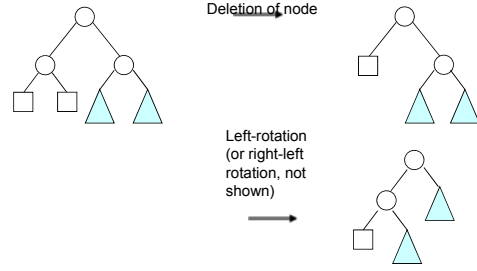

Subcase: right sibling has height 1. No readjustment needed. There is also the symmetric subcase.

31.05.2011 Theory 1 - AVL trees: deletion 4

Node has only leaves as its children

Subcase: height = 2

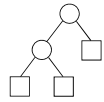

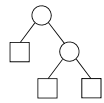

Deletion of node

Left-rotation (or right-left rotation, not shown)

Note: height may have decreased by 1! May need readjustment

31.05.2011 Theory 1 - AVL trees: deletion 5

Node has one internal node as child

Note that this illustration covers the two possible subcases. Height has decreased, which may need readjustment.

31.05.2011 Theory 1 - AVL trees: deletion 6

Node has two internal nodes as children

- First we proceed just like we do in standard search trees:
 1. Replace the content of the node to be deleted p by the content of its symmetrical successor q .
 2. Then delete node q .
- Since q can have at most one internal node as a child (the right one), cases 1 and 2 apply for q .

31.05.2011 Theory 1 - AVL trees: deletion 7

The method *upout*

- The method *upout* works similarly to *upin*.
- It is called recursively along the search path and adjusts the balance factors via rotations and double rotations.
- When *upout* is called for a node p , we have (see above):
 1. $bal(p) = 0$
 2. The height of the subtree rooted in p has decreased by 1.
- upout* will be called recursively as long as these conditions are fulfilled (invariant).
- Again, we distinguish 2 cases, depending on whether p is the left or the right child of its parent ϕp .
- Since the two cases are symmetrical, we only consider the case where p is the left child of ϕp .

31.05.2011 Theory 1 - AVL trees: deletion 8

Case 1.1: p is the left child of ϕp and $bal(\phi p) = -1$

- Since the height of the subtree rooted in p has decreased by 1, the balance factor of ϕp changes to 0.
- By this, the height of the subtree rooted in ϕp has also decreased by 1 and we have to call *upout*(ϕp) (the invariant now holds for ϕp).

31.05.2011 Theory 1 - AVL trees: deletion 9

Case 1.2: p is the left child of ϕp and $bal(\phi p) = 0$

- Since the height of the subtree rooted in p has decreased by 1, the balance factor of ϕp changes to 1.
- Then we are done, because the height of the subtree rooted in ϕp has not changed.

31.05.2011 Theory 1 - AVL trees: deletion 10

Case 1.3: p is the left child of ϕp and $bal(\phi p) = +1$

- Then the right subtree of ϕp was higher (by 1) than the left subtree before the deletion.
- Hence, in the subtree rooted in ϕp the AVL property is now violated.
- We distinguish three cases according to the balance factor of q .

31.05.2011 Theory 1 - AVL trees: deletion 11

Case 1.3.1: $bal(q) = 0$

31.05.2011 Theory 1 - AVL trees: deletion 12

Case 1.3.2: $bal(q) = +1$

left rotation

- Again, the height of the subtree has decreased by 1, while $bal(r) = 0$ (invariant).
- Hence we call $upout(r)$.

31.05.2011 Theory 1 - AVL trees: deletion 13

Case 1.3.3: $bal(q) = -1$

double rotation right-left

- Since $bal(q) = -1$, one of the trees 2 or 3 must have height h .
- Therefore, the height of the complete subtree has decreased by 1, while $bal(r) = 0$ (invariant).
- Hence, we again call $upout(r)$.

31.05.2011 Theory 1 - AVL trees: deletion 14

Observation

- Unlike insertions, deletions may cause recursive calls of $upout$ after a double rotation.
- Therefore, in general a single rotation or double rotation is not sufficient to rebalance the tree.
- There are examples where for all nodes along the search path rotations or double rotations must be carried out.
- Since $h \leq 1.44 \dots \log_2(n) + 1$, we may conclude that the deletion of a key from an AVL tree with n keys can be carried out in at most $O(\log n)$ steps.
- AVL trees are a *worst-case efficient* data structure for finding, inserting and deleting keys.
