8 Hashing: Open addressing

Summer Term 2011

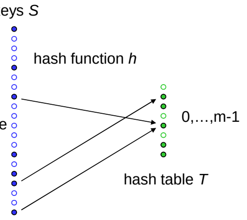
Jan-Georg Smaus

Albert-Ludwigs-Universität Freiburg

Hashing: General Framework

Set of keys S

Univer-se U of all possible keys



$h(s)$ = hash address

$h(s) = h(s')$ $\Leftrightarrow$ s and s' are synonyms with respect to h; address collision

Possible ways of treating collisions

- Collisions are treated differently in different methods.
- A data set with key s is called a colliding element if bucket $B_{h(s)}$ is already taken by another data set.
- What can we do with colliding elements?
  1. Chaining: We learned about that in the last chapter.
  2. Open Addressing: Colliding elements are stored in other vacant buckets. During storage and lookup, these are found through so-called probing.

Open addressing

Idea:

Store colliding elements in vacant ("open") buckets of the hash table
If $T[h(k)]$ is taken, find a different bucket for k according to a fixed rule

Example:

Consider the bucket with the next smaller index:

$(h(k) - 1) \bmod m$

General:

Consider the sequence

$(h(k) - j) \bmod m$

$j = 0, \ldots, m-1$

Probe sequence

Even more general:

Consider the probe sequence

$(h(k) - s(j,k)) \bmod m$

$j = 0, \ldots, m-1$, for a given function $s(j,k)$

Examples for the function

$s(j,k) = j$ linear probing

$s(j,k) = (-1)^j * \lceil \frac{j}{2} \rceil^2$ quadratic probing

We will now look at these …

Others: uniform probing, random probing, double hashing

Probe sequence

Properties of $s(j,k)$

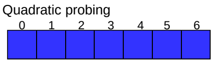
Sequence

$(h(k) - s(0,k)) \bmod m$,
$(h(k) - s(1,k)) \bmod m$,

$(h(k) - s(m-2,k)) \bmod m$,
$(h(k) - s(m-1,k)) \bmod m$

should result in a permutation of $0, \ldots, m-1$.

Example: Quadratic probing



$h(11) = 4$

$s(j,k) = -1,1,-4,4,-9,9$

Critical:

Deletion of data sets → mark as deleted

(Insert 4, 18, 25; delete 4; lookup 18, 25)

Open addressing

```
class OpenHashTable extends HashTable {
        // in HashTable: TableEntry [] T;
        private int [] tag;
        static final int EMPTY = 0;
        static final int OCCUPIED = 1;
        static final int DELETED = 2;
        // Constructor
        OpenHashTable (int capacity) {
            super(capacity);
            tag = new int [capacity];
            for (int i = 0; i < capacity; i++) {
                tag[i] = EMPTY;
            }
        }
        // The hash function
        protected int h (Object key) {...}
        // Function s for probe sequence
        protected int s (int j, Object key) {
            // quadratic probing
            if (j % 2 == 0)
                return ((j + 1) / 2) * ((j + 1) / 2);
            else
                return -((j + 1) / 2) * ((j + 1) / 2);
            }
```

Open addressing - lookup

```
public int searchIndex (Object key) {
        /* searches for an entry with the given key in the hash table and
           returns the respective index or -1 */
        int i = h(key);
        int j = 1;  // next index of probing sequence
        while (tag[i] != EMPTY &&!key.equals(T[i].key)){
            // Next entry in probing sequence
            i = (h(key) - s(j++, key)) % capacity;
            if (i < 0)
                i = i + capacity;
        }
        if (key.equals(T[i].key) && tag[i] == OCCUPIED)
            return i;
        else
            return -1;
    }
    public Object search (Object key) {
        /* searches for an entry with the given key in the hash table and
           returns the respective value or NULL */
        int i = searchIndex (key);
        if (i >= 0)
            return T[i].value;
        else
            return null;
    }
```

Open addressing - insert

```
public void insert (Object key, Object value) {
        // inserts an entry with the given key and value
        int j = 1;  // next index of probing sequence
        int i = h(key);
        while (tag[i] == OCCUPIED) {
            i = (h(key) - s(j++, key)) % capacity;
            if (i < 0)
                i = i + capacity;
        }
        T[i] = new TableEntry(key, value);
        tag[i] = OCCUPIED;
    }
```

Open addressing - delete

```
public void delete (Object key) {
        // deletes entry with given key from the hash table
        int i = searchIndex(key);
        if (i >= 0) {
            // Successful search
            tag[i] = DELETED;
         }
    }
```

Test program

```
public class OpenHashingTest {
        public static void main(String args[]) {
            Integer[] t= new Integer[args.length];
            for (int i = 0; i < args.length; i++)
                t[i] = Integer.valueOf(args[i]);
            OpenHashTable h = new OpenHashTable (7);
            for (int i = 0; i <= t.length - 1; i++) {
                h.insert(t[i], null);#
                h.printTable ();
            }
            h.delete(t[0]); h.delete(t[1]);
            h.delete(t[6]); h.printTable();
        }
    }
```

Call:

```
java OpenHashingTest 12 53 5 15 2 19 43
```

Output (quadratic probing):

```
[ ]  [ ]  [ ]  [ ]  [ ]  (12) [ ]
[ ]  [ ]  [ ]  [ ]  (53) (12) [ ]
[ ]  [ ]  [ ]  [ ]  (53) (12) (5)
[ ]  (15) [ ]  [ ]  (53) (12) (5)
[ ]  (15) (2)  [ ]  (53) (12) (5)
(19) (15) (2)  [ ]  (53) (12) (5)
(19) (15) (2)  (43) (53) (12) (5)

(19) (15) (2)  {43} {53} {12} (5)
```

Probe sequences – linear probing

$s(j,k) = j$

Probe sequence for k:

$h(k)$, $h(k)$-1, ..., 0, m-1, ..., $h(k)$+1,

Problem:

"primary clustering"

0	1	2	3	4	5	6
			5	53	12	

Pr (next object ends at position 2) = 4/7

Pr (next object ends at position 1) = 1/7

Long chains are extended with higher probability than short ones.

Efficiency of linear probing

Successful search:

$$C_n \approx \frac{1}{2}\left(1+\frac{1}{(1-\alpha)}\right)$$

Failed search:

$$C'_n \approx \frac{1}{2}\left(1+\frac{1}{(1-\alpha)^2}\right)$$

α	C_n (successful)	C'_n (failed)
0.50	1.5	2.5
0.90	5.5	50.5
0.95	10.5	200.5
1.00	-	-

Efficiency of linear probing decreases drastically as soon as the load factor α gets close to the value 1.

Quadratic probing

$$s(j,k) = (-1)^j * \lceil \tfrac{j}{2} \rceil^2$$

Probe sequence for *k*:

h(*k*), *h*(*k*)+1, *h*(*k*)-1, *h*(*k*)+4, ...

Permutation, if *m* = is a prime of the form *4i + 3*, for some *i.*

Problem: secondary clustering, i.e. two synonyms *k* and *k´* always run through the same probe sequence.

Efficiency of quadratic probing

Successful search:

$$C_n \approx 1 - \frac{\alpha}{2} + ln\left(\frac{1}{(1-\alpha)}\right)$$

Failed search:

$$C'_n \approx \frac{1}{1-\alpha} - \alpha + ln\left(\frac{1}{(1-\alpha)}\right)$$

α	C_n (successful)	C'_n(failed)
0.50	1.44	2.19
0.90	2.85	11.40
0.95	3.52	22.05
1.00	-	-
