

Definition

Model checking is an automated technique that, given a finite-state model of a system and a formal property, systematically checks whether this property holds for (a given state in) that model.

- Model of the system \Rightarrow How the system actually behaves.
- Formal properties \Rightarrow How the system should behave.
 - Safety: something bad never happen
 - Liveness: something good eventually happens
 - Fairness: if something may happen frequently, it will happen

Runtime Verification

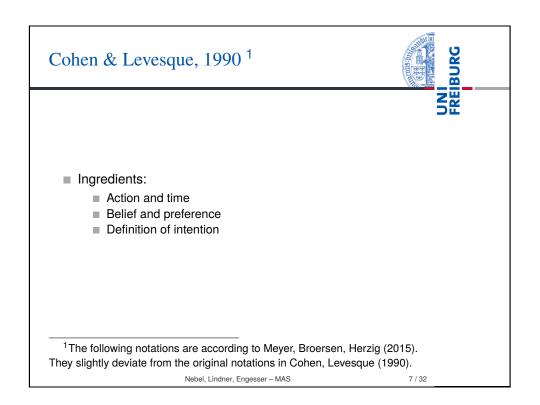

5/32

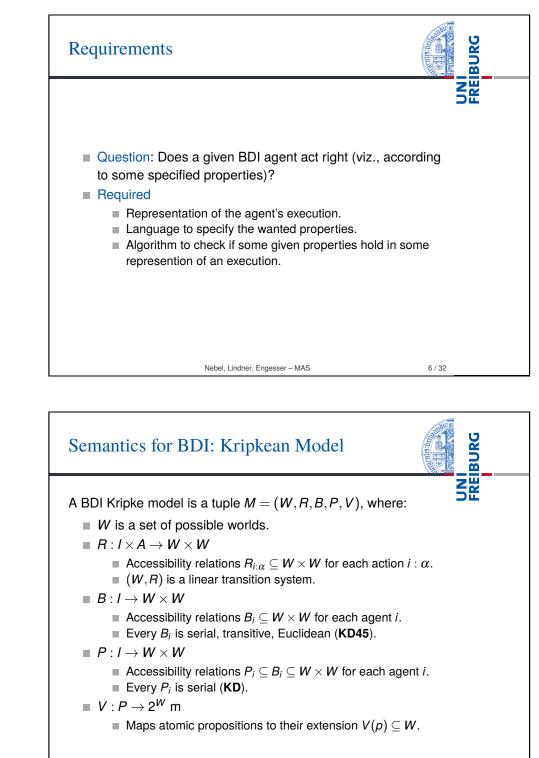

Definition

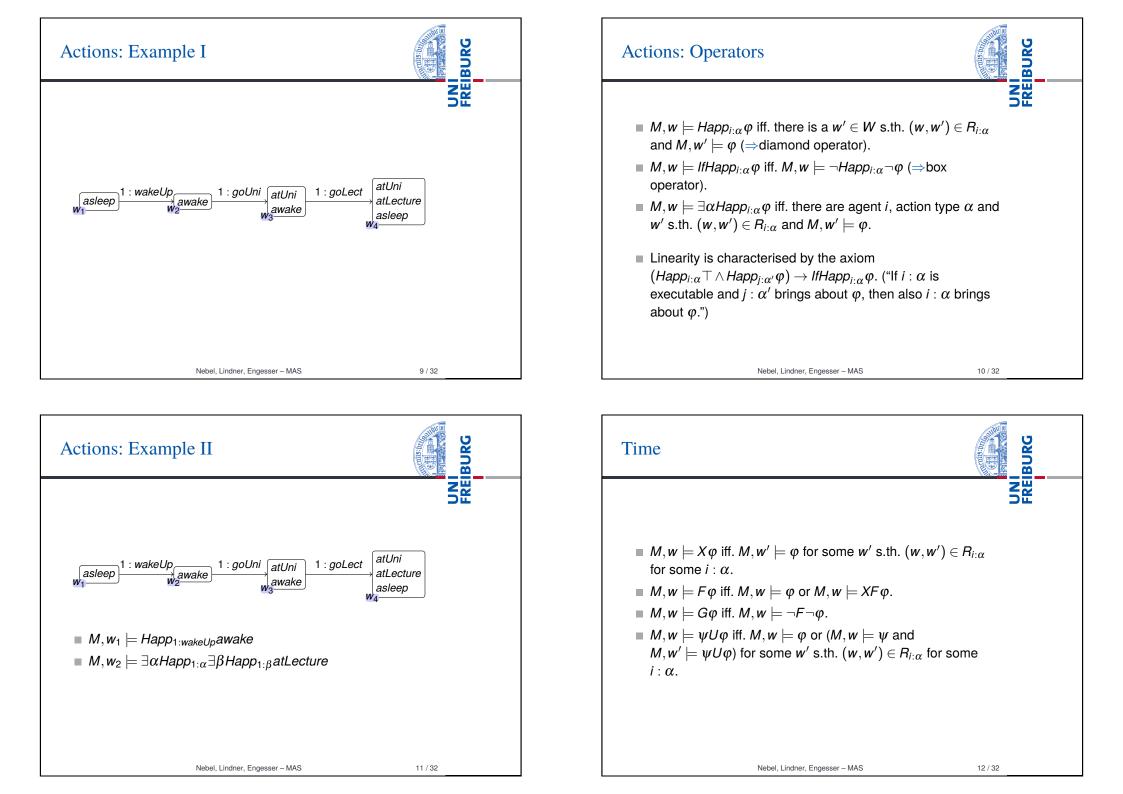

Runtime verification is the discipline of computer science that deals with the study, development, and application of those verification techniques that allow checking whether a run of a system under scrutiny satisfies or violates a given correctness property.

 \Rightarrow Testing using formal methods.

The Nell problem

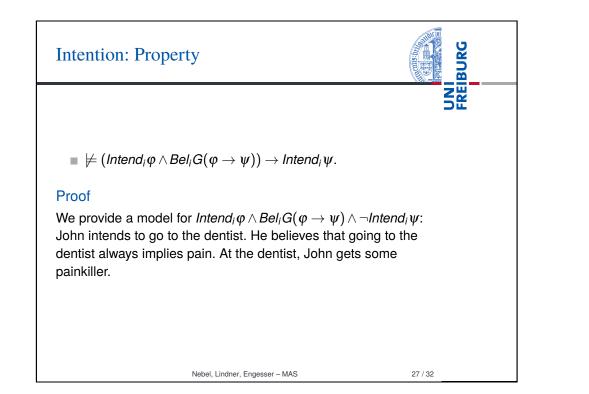

UNI FREIBURG Say a problem solver is confronted with the classic situation of a heroine, called Nell, having been tied to the tracks while a train approaches. The problem solver, called Dudley, knows that "If Nell is going to be mashed, I must remove her from the tracks." When Dudley deduces that he must do something, he looks for, and eventually executes, a plan for doing it. This will involve finding out where Nell is, and making a navigation plan to get to her location. Assume that he knows where she is, and he is not too far away; then the fact that the plan will be carried out will be added to Dudley's world model. Dudley must have some kind of database consistency maintainer to make sure that the plan is deleted if it is no longer necessary. Unfortunately, as soon as an apparently successful plan is added to the world model, the consistency maintainer will notice that "Nell is going to be mashed" is no longer true. But that removes any justification for the plan, so it goes too. But that means "Nell is going to be mashed" is no longer contradictory, so it comes back in. And so forth.

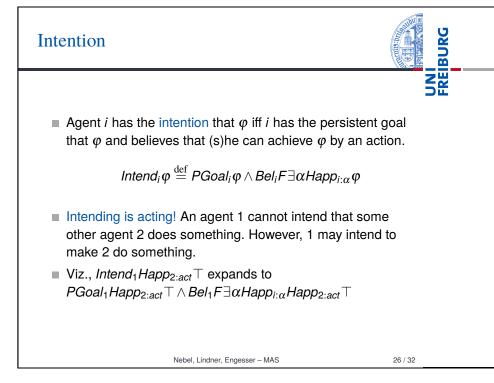

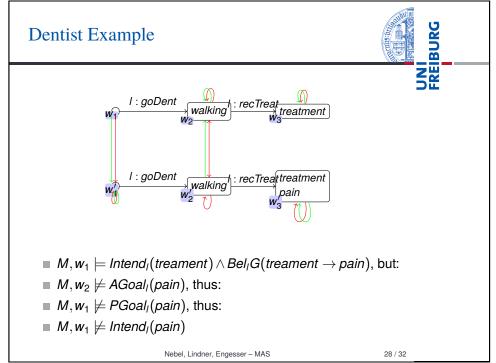

Achievement Goal: Too weak for Intention

Persistent Goal

Remark: Runtime Verification

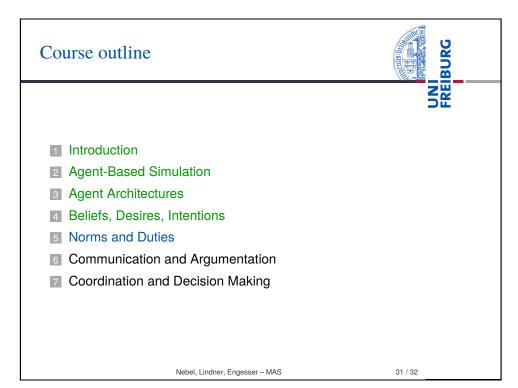

29/32

Sketch

- Observe the execution of the system to be verified (e.g., log state of the environment, mental state of the agents, the agents' actions).
- Represent the execution log using the semantics of Cohen & Levesque.
- Model check representation against the agents' specification, e.g.:
 - $\blacksquare G(goldNear \rightarrow Intend(hasGold))$
 - $\blacksquare G(Bel(goldNear) \rightarrow Intend(hasGold))$
 - $\blacksquare G(battLow \rightarrow Intend(\neg battLow))$
- If ind time points where the specification evaluates false \Rightarrow Fault detection.

Recap and Outlook

- We have studied an integrated logical framework that captures many aspects of agent behavior taking belief and knowledge, preferences, goals, and intentions into account, as well as how these mental attitutes change through time as progressed by actions.
- Next time, we'll look at another important notion, obligations and permissions, and we'll briefly discuss a practical framework (BOID) that deals with decision making in light of conflicts between beliefs, desires, intentions, and obligations.
