Introduction Nodes and states

### Our plan for the next lectures

#### Choices to make:

- 1. search direction: progression/regression/both
  - → previous chapter
- 2. search space representation: states/sets of states
  - → previous chapter
- 3. search algorithm: uninformed/heuristic; systematic/local
  - → this chapter
- 4. search control: heuristics, pruning techniques
  - → next chapters

### Principles of Al Planning

November 11th, 2008 — 6. State-space search: search algorithms

#### Introduction to search algorithms for planning

Search nodes & search states Search for planning Common procedures for search algorithms

Uninformed search algorithms

#### Heuristic search algorithms

Heuristics: definition and properties Systematic heuristic search algorithms Heuristic local search algorithms

M. Helmert (Universität Freiburg)

Nodes and states

#### Search

- ► Search algorithms are used to find solutions (plans) for transition systems in general, not just for planning tasks.
- ▶ Planning is one application of search among many.
- ▶ In this chapter, we describe some popular and/or representative search algorithms, and (the basics of) how they apply to planning.
- Most of this is review of material that should be known (details: Russell and Norvig's textbook).

M. Helmert (Universität Freiburg) Al Planning November 11th, 2008 M. Helmert (Universität Freiburg) Al Planning November 11th, 2008

#### Search states vs. search nodes

In search, one distinguishes:

- ▶ search states s → states (vertices) of the transition system
- ▶ search nodes  $\sigma \leadsto$  search states plus information on where/when/how they are encountered during search

#### What is in a search node?

Different search algorithms store different information in a search node  $\sigma$ , but typical information includes:

- $\triangleright$  state( $\sigma$ ): associated search state
- **parent**( $\sigma$ ): pointer to search node from which  $\sigma$  is reached
- ▶  $action(\sigma)$ : an action/operator leading from  $state(parent(\sigma))$  to  $state(\sigma)$
- $g(\sigma)$ : cost of  $\sigma$  (length of path from the root node)

For the root node,  $parent(\sigma)$  and  $action(\sigma)$  are undefined.

M. Helmert (Universität Freiburg)

Introduction Nodes and states

### Required ingredients for search

A general search algorithm can be applied to any transition system for which we can define the following three operations:

- ▶ init(): generate the initial state
- ▶ is-goal(s): test if a given state is a goal state
- ▶ succ(s): generate the set of successor states of state s, along with the operators through which they are reached (represented as pairs  $\langle o, s' \rangle$  of operators and states)

Together, these three functions form a search space (a very similar notion to a transition system).

### Search states vs. planning states

Search states  $\neq$  (planning) states:

- ► Search states don't have to correspond to states in the planning sense.
  - ▶ progression: search states  $\approx$  (planning) states
  - regression: search states  $\approx$  sets of states (formulae)
- ► Search algorithms for planning where search states are planning states are called state-space search algorithms.
- ► Strictly speaking, regression is **not** an example of state-space search, although the term is often used loosely.
- ► However, we will put the emphasis on progression, which is almost always state-space search.

18 6

Introduction Search for planning

### Search for planning: progression

Let  $\Pi = \langle A, I, O, G \rangle$  be a planning task.

Search space for progression search

states: all states of  $\Pi$  (assignments to A)

- ► init() = *I*
- $\blacktriangleright \, \mathsf{succ}(s) = \{ \langle o, s' \rangle \mid o \in O, s' = \mathsf{app}_o(s) \}$
- $is\text{-goal}(s) = \begin{cases} \text{true} & \text{if } s \models G \\ \text{false} & \text{otherwise} \end{cases}$

Introduction Search for planning

# Search for planning: regression

Let  $\langle A, I, O, G \rangle$  be a planning task.

Search space for regression search

states: all formulae over A

- ▶ init() = *G*
- ▶  $\operatorname{succ}(\phi) = \{ \langle o, \phi' \rangle \mid o \in O, \phi' = \operatorname{regr}_o(\phi), \phi' \text{ is satisfiable} \}$  (modified if splitting is used)
- $is-goal(\phi) = \begin{cases} true & \text{if } I \models \phi \\ false & \text{otherwise} \end{cases}$

Classification of search algorithms

uninformed search vs. heuristic search:

- uninformed search algorithms only use the basic ingredients for general search algorithms
- ► heuristic search algorithms additionally use heuristic functions which estimate how close a node is to the goal

systematic search vs. local search:

- systematic algorithms consider a large number of search nodes simultaneously
- ► local search algorithms work with one (or a few) candidate solutions (search nodes) at a time
- ▶ not a black-and-white distinction; there are crossbreeds (e.g., enforced hill-climbing)

M. Helmert (Universität Freiburg)

Al Planning

November 11th, 2008

10 / 43

Introduction Search for planning

### Classification: what works where in planning?

uninformed vs. heuristic search:

- ► For satisficing planning, heuristic search vastly outperforms uninformed algorithms on most domains.
- ► For optimal planning, the difference is less pronounced. An efficiently implemented uninformed algorithm is not easy to beat in most domains.

systematic search vs. local search:

- ► For satisficing planning, the most successful algorithms are somewhere between the two extremes.
- ▶ For optimal planning, systematic algorithms are required.

Introduction Common procedure

### Common procedures for search algorithms

Before we describe the different search algorithms, we introduce three procedures used by all of them:

- ▶ make-root-node: Create a search node without parent.
- ► make-node: Create a search node for a state generated as the successor of another state.
- extract-solution: Extract a solution from a search node representing a goal state.

M. Helmert (Universität Freiburg)

Al Planning

November 11th, 2008

11 / 43

M. H

M. Helmert (Universität Freiburg) Al Planning

November 11th, 2008

### Procedure make-root-node

make-root-node: Create a search node without parent.

#### Procedure make-root-node

```
def make-root-node(s):
      \sigma := \mathbf{new} \text{ node}
      state(\sigma) := s
      parent(\sigma) := undefined
      action(\sigma) := undefined
      g(\sigma) := 0
      return \sigma
```

M. Helmert (Universität Freiburg)

Al Planning

November 11th, 2008

13 / 43

#### Procedure make-node

make-node: Create a search node for a state generated as the successor of another state.

#### Procedure make-node

```
def make-node(\sigma, o, s):
      \sigma' := \mathbf{new} \text{ node}
      state(\sigma') := s
      parent(\sigma') := \sigma
      action(\sigma') := o
      g(\sigma') := g(\sigma) + 1
       return \sigma'
```

M. Helmert (Universität Freiburg)

Al Planning

November 11th, 2008

14 / 43

#### Procedure extract-solution

extract-solution: Extract a solution from a search node representing a goal state.

#### Procedure extract-solution

```
def extract-solution(\sigma):
     solution := new list
     while parent(\sigma) is defined:
           solution.push-front(action(\sigma))
           \sigma := parent(\sigma)
     return solution
```

Uninformed search

# Uninformed search algorithms

- ▶ Uninformed algorithms are less relevant for planning than heuristic ones, so we keep their discussion brief.
- ▶ Uninformed algorithms are mostly interesting to us because we can compare and contrast them to related heuristic search algorithms.

Popular uninformed systematic search algorithms:

- breadth-first search
- ▶ depth-first search
- ▶ iterated depth-first search

Popular uninformed local search algorithms:

random walk

M. Helmert (Universität Freiburg)

Al Planning

November 11th, 2008

16 / 43

Uninformed search

### Breadth-first search without duplicate detection

```
\begin{aligned} & \textbf{Breadth-first search} \\ & \textit{queue} := \textbf{new} \text{ fifo-queue} \\ & \textit{queue.push-back}(\text{make-root-node}(\text{init}())) \\ & \textbf{while not } \textit{queue.empty}() : \\ & \sigma = \textit{queue.pop-front}() \\ & \textbf{if is-goal}(\text{state}(\sigma)) : \\ & \textbf{return } \text{ extract-solution}(\sigma) \\ & \textbf{for each } \langle o, s \rangle \in \text{succ}(\textit{state}(\sigma)) : \\ & \sigma' := \text{make-node}(\sigma, o, s) \\ & \textit{queue.push-back}(\sigma') \\ & \textbf{return } \text{ unsolvable} \end{aligned}
```

- ▶ Possible improvement: duplicate detection (see next slide).
- ▶ Another possible improvement: test if  $\sigma'$  is a goal node; if so, terminate immediately. (We don't do this because it obscures the similarity to some of the later algorithms.)

Random walk

#### Random walk

```
\begin{split} \sigma := \mathsf{make}\text{-root-node}(\mathsf{init}()) \\ \textbf{forever}: \\ & \quad \textbf{if is-goal}(\mathsf{state}(\sigma)): \\ & \quad \textbf{return extract-solution}(\sigma) \\ & \quad \mathsf{Choose a random element } \langle o, s \rangle \text{ from } \mathsf{succ}(\mathsf{state}(\sigma)). \\ & \quad \sigma := \mathsf{make-node}(\sigma, o, s) \end{split}
```

Uninformed search

- ► The algorithm usually does not find any solutions, unless almost every sequence of actions is a plan.
- ▶ Often, it runs indefinitely without making progress.
- ▶ It can also fail by reaching a dead end, a state with no successors. This is a weakness of many local search approaches.

M. Helmert (Universität Freiburg)

Al Planning

November 11th, 2008

# Heuristic search algorithms: systematic

► Heuristic search algorithms are the most common and overall most successful algorithms for classical planning.

Popular systematic heuristic search algorithms:

- ▶ greedy best-first search
- ► A\*
- weighted A\*
- ► IDA\*
- ▶ depth-first branch-and-bound search
- breadth-first heuristic search

Heuristic search

Heuristics

### Heuristic search: idea

Heuristic search Heurist

# Required ingredients for heuristic search

A heuristic search algorithm requires one more operation in addition to the definition of a search space.

Definition (heuristic function)

Let  $\Sigma$  be the set of nodes of a given search space.

A heuristic function or heuristic (for that search space) is a function  $h: \Sigma \to \mathbb{N}_0 \cup \{\infty\}$ .

The value  $h(\sigma)$  is called the heuristic estimate or heuristic value of heuristic h for node  $\sigma$ . It is supposed to estimate the distance from  $\sigma$  to the nearest goal node.

M. Helmert (Universität Freiburg)

Al Planning

November 11th, 2008 24 / 43

M. Helmert (Universität Freiburg)

Al Planning

November 11th, 2008

#### Heuristic search Heuristi

### What exactly is a heuristic estimate?

What does it mean that h "estimates the goal distance"?

- ► For most heuristic search algorithms, *h* does not need to have any strong properties for the algorithm to work (= be correct and complete).
- ► However, the efficiency of the algorithm closely relates to how accurately *h* reflects the actual goal distance.
- ▶ For some algorithms, like A\*, we can prove strong formal relationships between properties of h and properties of the algorithm (optimality, dominance, run-time for bounded error, ...)
- ► For other search algorithms, "it works well in practice" is often as good an analysis as one gets.

M. Helmert (Universität Freiburg)

Al Planning

November 11th, 2008

25 / 43

### Heuristics applied to nodes or states?

- ▶ Most texts apply heuristic functions to states, not nodes.
- ► This is slightly less general than our definition:
  - ▶ Given a state heuristic h, we can define an equivalent node heuristic as  $h'(\sigma) := h(state(\sigma))$ .
  - ► The opposite is not possible. (Why not?)
- ► There is good justification for only allowing state-defined heuristics: why should the estimated distance to the goal depend on how we ended up in a given state *s*?
- We call heuristics which don't just depend on  $state(\sigma)$  pseudo-heuristics.
- In practice there are sometimes good reasons to have the heuristic value depend on the generating path of  $\sigma$  (e.g., the landmark pseudo-heuristic, Richter et al. 2008).

M. Helmert (Universität Freiburg)

Al Planning

November 11th, 2008

26 / 43

Heuristic search Heuristics

#### Perfect heuristic

Let  $\Sigma$  be the set of nodes of a given search space.

Definition (optimal/perfect heuristic)

The optimal or perfect heuristic of a search space is the heuristic  $h^*$  which maps each search node  $\sigma$  to the length of a shortest path from  $state(\sigma)$  to any goal state.

Note:  $h^*(\sigma) = \infty$  iff no goal state is reachable from  $\sigma$ .

Heuristic search Heuristic

### Properties of heuristics

A heuristic h is called

- ▶ safe if  $h^*(\sigma) = \infty$  for all  $\sigma \in \Sigma$  with  $h(\sigma) = \infty$
- ▶ goal-aware if  $h(\sigma) = 0$  for all goal nodes  $\sigma \in \Sigma$
- ▶ admissible if  $h(\sigma) \le h^*(\sigma)$  for all nodes  $\sigma \in \Sigma$
- ▶ consistent if  $h(\sigma) \le h(\sigma') + 1$  for all nodes  $\sigma, \sigma' \in \Sigma$  such that  $\sigma'$  is a successor of  $\sigma$

Systematic search

# Weighted A\*

```
Weighted A* (with duplicate detection and reopening)
```

Heuristic search

```
open := new min-heap ordered by (\sigma \mapsto g(\sigma) + W \cdot h(\sigma))
open.insert(make-root-node(init()))
closed := \emptyset
distance := \emptyset
while not open.empty():
      \sigma = open.pop-min()
     if state(\sigma) \notin closed or g(\sigma) < distance(state(\sigma)):
            closed := closed \cup \{state(\sigma)\}
             distance(\sigma) := g(\sigma)
            if is-goal(state(\sigma)):
                   return extract-solution(\sigma)
             for each \langle o, s \rangle \in \text{succ}(state(\sigma)):
                   \sigma' := \mathsf{make-node}(\sigma, o, s)
                   if h(\sigma') < \infty:
                          open.insert(\sigma')
return unsolvable
```

Heuristic search Systematic search

### Properties of A\*

- ▶ the most commonly used algorithm for optimal planning
- rarely used for satisficing planning
- complete for safe heuristics (even without duplicate detection)
- optimal if h is admissible and/or consistent (even without duplicate detection)
- ▶ never reopens nodes if *h* is consistent

#### Implementation notes:

- ▶ in the heap-ordering procedure, it is considered a good idea to break ties in favour of lower *h* values
- can simplify algorithm if we know that we only have to deal with consistent heuristics
- common, hard to spot bug: test membership in *closed* at the wrong time

M. Helmert (Universität Freiburg)

Al Planning

November 11th, 2008

38 / 43

Heuristic search Systematic search

### Properties of weighted A\*

The weight  $W \in \mathbb{R}_0^+$  is a parameter of the algorithm.

- for W = 0, behaves like breadth-first search
- ▶ for W = 1, behaves like A\*
- lacktriangleright for  $W o\infty$ , behaves like greedy best-first search

#### Properties:

- one of the three most commonly used algorithms for satisficing planning
- ▶ for W > 1, can prove similar properties to A\*, replacing optimal with bounded suboptimal: generated solutions are at most a factor W as long as optimal ones

M. Helmert (Universität Freiburg) Al Planning November 11th, 2008 40 / 43

Heuristic search Local search

### Hill-climbing

```
Hill-climbing \begin{split} \sigma &:= \mathsf{make}\text{-root-node}(\mathsf{init}()) \\ \textbf{forever} &: \\ &\quad \textbf{if is-goal}(\mathsf{state}(\sigma)) \\ &\quad \textbf{return extract-solution}(\sigma) \\ &\quad \Sigma' := \{ \, \mathsf{make}\text{-node}(\sigma,o,s) \mid \langle o,s \rangle \in \mathsf{succ}(\mathsf{state}(\sigma)) \, \} \\ &\quad \sigma := \mathsf{an element of } \Sigma' \ \mathsf{minimizing} \ h \ \mathsf{(random tie breaking)} \end{split}
```

- ightharpoonup can easily get stuck in local minima where immediate improvements of  $h(\sigma)$  are not possible
- ▶ many variations: tie-breaking strategies, restarts

M. Helmert (Universität Freiburg)
