Summary

## General procedure for obtaining a heuristic

Solve an easier version of the problem.

Two common methods:

- **relaxation**: consider **less constrained** version of the problem
- **abstraction**: consider **smaller** version of real problem

In previous chapters, we have studied **relaxation**, which has been very successfully applied to **satisficing planning**.

Now, we study **abstraction**, which is one of the most prominent techniques for **optimal planning**.

Outlook

Abstractions:  
formally

Summary

Abstracting a transition system means **dropping some distinctions** between states, while **preserving the transition behaviour** as much as possible.

- An abstraction of a transition system  $\mathcal{T}$  is defined by an **abstraction mapping**  $\alpha$  that defines which states of  $\mathcal{T}$  should be distinguished and which ones should not.
- From  $\mathcal{T}$  and  $\alpha$ , we compute an **abstract transition system**  $\mathcal{T}'$  which is similar to  $\mathcal{T}$ , but smaller.
- The **abstract goal distances** (goal distances in  $\mathcal{T}'$ ) are used as heuristic estimates for goal distances in  $\mathcal{T}$ .

Summary

## Example (15-puzzle)

A **15-puzzle** state is given by a permutation  $\langle b, t_1, \dots, t_{15} \rangle$  of  $\{1, \dots, 16\}$ , where  $b$  denotes the blank position and the other components denote the positions of the 15 tiles.

One possible **abstraction mapping** ignores the precise location of tiles 8–15, i. e., two states are distinguished iff they differ in the position of the blank or one of the tiles 1–7:

$$\alpha(\langle b, t_1, \dots, t_{15} \rangle) = \langle b, t_1, \dots, t_7 \rangle$$

The heuristic values for this abstraction correspond to the cost of moving tiles 1–7 to their goal positions.

- $16 \cdot 15 \cdot \dots \cdot 9 = 518918400 \approx 5 \cdot 10^8$  reachable states

Given  $\mathcal{T}$  and  $\alpha$ , how do we compute  $\mathcal{T}'$ ?

## Requirement

We want to obtain an **admissible heuristic**.

Hence,  $h^*(\alpha(s))$  (in the abstract state space  $\mathcal{T}'$ ) should never overestimate  $h^*(s)$  (in the concrete state space  $\mathcal{T}$ ).

An easy way to achieve this is to ensure that **all solutions in  $\mathcal{T}$  also exist in  $\mathcal{T}'$** :

- If  $s$  is a goal state in  $\mathcal{T}$ , then  $\alpha(s)$  is a goal state in  $\mathcal{T}'$ .
- If  $\mathcal{T}$  has a transition from  $s$  to  $t$ , then  $\mathcal{T}'$  has a transition from  $\alpha(s)$  to  $\alpha(t)$ .

# Computing the abstract transition system: example

## Example (15-puzzle)

In the running example:

- $\mathcal{T}$  has the unique goal state  $\langle 16, 1, 2, \dots, 15 \rangle$ .
  - ↪  $\mathcal{T}'$  has the unique goal state  $\langle 16, 1, 2, \dots, 7 \rangle$ .
- Let  $x$  and  $y$  be neighboring positions in the  $4 \times 4$  grid.
  - $\mathcal{T}$  has a transition from  $\langle x, t_1, \dots, t_{i-1}, y, t_{i+1}, \dots, t_{15} \rangle$  to  $\langle y, t_1, \dots, t_{i-1}, x, t_{i+1}, \dots, t_{15} \rangle$  for all  $i \in \{1, \dots, 15\}$ .
    - ↪  $\mathcal{T}'$  has a transition from  $\langle x, t_1, \dots, t_{i-1}, y, t_{i+1}, \dots, t_7 \rangle$  to  $\langle y, t_1, \dots, t_{i-1}, x, t_{i+1}, \dots, t_7 \rangle$  for all  $i \in \{1, \dots, 7\}$ .
    - ↪ Moreover,  $\mathcal{T}'$  has a transition from  $\langle x, t_1, \dots, t_7 \rangle$  to  $\langle y, t_1, \dots, t_7 \rangle$  if  $y \notin \{t_1, \dots, t_7\}$ .

Introduction  
Practical  
requirements  
Multiple  
abstractions  
Outlook

Abstractions:  
formally

Summary

To be useful in practice, an abstraction heuristic must be efficiently computable. This gives us two requirements for  $\alpha$ :

- For a given state  $s$ , the **abstract state**  $\alpha(s)$  must be efficiently computable.
- For a given abstract state  $\alpha(s)$ , the **abstract goal distance**  $h^*(\alpha(s))$  must be efficiently computable.

There are different ways of achieving these requirements:

- **pattern database heuristics** (Culberson & Schaeffer, 1996)
- **merge-and-shrink abstractions** (Dräger, Finkbeiner & Podelski, 2006)
- **structural patterns** (Katz & Domshlak, 2008b)
  - not covered in this course

Summary

# Practical requirements for abstractions: example

## Example (15-puzzle)

In our running example,  $\alpha$  can be very efficiently computed: just project the given 16-tuple to its first 8 components.

To compute abstract goal distances efficiently during search, most common algorithms precompute **all abstract goal distances** prior to search by performing a backward breadth-first search from the goal state(s). The distances are then stored in a table (requires about 495 MB of RAM). During search, computing  $h^*(\alpha(s))$  is just a table lookup.

This heuristic is an example of a **pattern database heuristic**.

Abstractions:  
informally

Introduction

Practical  
requirements

Multiple  
abstractions

Outlook

Abstractions:  
formally

Summary

- One important practical question is how to come up with a suitable abstraction mapping  $\alpha$ .
- Indeed, there is usually a **huge number of possibilities**, and it is important to pick good abstractions (i. e., ones that lead to informative heuristics).
- However, it is generally **not necessary to commit to a single abstraction**.

Abstractions:  
informally

Introduction

Practical  
requirements

**Multiple  
abstractions**

Outlook

Abstractions:  
formally

Summary

## Maximizing several abstractions:

- Each abstraction mapping gives rise to an admissible heuristic.
- By computing the **maximum** of several admissible heuristics, we obtain another admissible heuristic which **dominates** the component heuristics.
- Thus, we can always compute several abstractions and maximize over the individual abstract goal distances.

## Adding several abstractions:

- In some cases, we can even compute the **sum** of individual estimates and still stay admissible.
- Summation often leads to **much higher estimates** than maximization, so it is **important to understand when it is admissible**.

Summary

Reminder from Chapter 2:

## Definition (transition system)

A **transition system** is a 5-tuple  $\mathcal{T} = \langle S, L, T, s_0, S_\star \rangle$  where

- $S$  is a finite set of **states**,
- $L$  is a finite set of (transition) **labels**,
- $T \subseteq S \times L \times S$  is the **transition relation**,
- $s_0 \in S$  is the **initial state**, and
- $S_\star \subseteq S$  is the set of **goal states**.

We say that  $\mathcal{T}$  **has the transition**  $\langle s, l, s' \rangle$  if  $\langle s, l, s' \rangle \in T$ .

We also write this  $s \xrightarrow{l} s'$ , or  $s \rightarrow s'$  when not interested in  $l$ .

## Definition (induced abstractions)

Let  $\mathcal{T} = \langle S, L, T, s_0, S_\star \rangle$  be a transition system, and let  $\alpha : S \rightarrow S'$  be a surjective function.

The **abstraction (of  $\mathcal{T}$ ) induced by  $\alpha$** , in symbols  $\mathcal{T}^\alpha$ , is the transition system  $\mathcal{T}^\alpha = \langle S', L, T', s'_0, S'_\star \rangle$  defined by:

- $T' = \{ \langle \alpha(s), \ell, \alpha(t) \rangle \mid \langle s, \ell, t \rangle \in T \}$
- $s'_0 = \alpha(s_0)$
- $S'_\star = \{ \alpha(s) \mid s \in S_\star \}$

**Note:** It is easy to see that  $\mathcal{T}^\alpha$  is an abstraction of  $\mathcal{T}$ . It is the “**smallest**” abstraction of  $\mathcal{T}$  with abstraction mapping  $\alpha$ .

Summary

## Theorem (consistency and admissibility of $h^{\mathcal{A}, \alpha}$ )

Let  $\Pi$  be an FDR planning task, and let  $\mathcal{A}$  be an abstraction of  $\mathcal{T}(\Pi)$  with abstraction mapping  $\alpha$ .

Then  $h^{\mathcal{A}, \alpha}$  is safe, goal-aware, admissible and consistent.

## Proof.

We prove goal-awareness and consistency; the other properties follow from these two.

Let  $\mathcal{T} = \mathcal{T}(\Pi) = \langle S, L, T, s_0, S_* \rangle$  and  $\mathcal{A} = \langle S', L', T', s'_0, S'_* \rangle$ .

Goal-awareness: We need to show that  $h^{\mathcal{A}, \alpha}(s) = 0$  for all  $s \in S_*$ , so let  $s \in S_*$ . Then  $\alpha(s) \in S'_*$  by the definition of abstractions and abstraction mappings, and hence  $h^{\mathcal{A}, \alpha}(s) = h^*_{\mathcal{A}}(\alpha(s)) = 0$ .

Since  $t$  is a successor of  $s$ , there exists an operator  $o$  with  $app_o(s) = t$  and hence  $\langle s, o, t \rangle \in T$ .

By the definition of abstractions and abstraction mappings, we get  $\langle \alpha(s), o, \alpha(t) \rangle \in T' \rightsquigarrow \alpha(t)$  is a successor of  $\alpha(s)$  in  $\mathcal{A}$ .

Therefore,  $h^{\mathcal{A}, \alpha}(s) = h_{\mathcal{A}}^*(\alpha(s)) \leq h_{\mathcal{A}}^*(\alpha(t)) + 1 = h^{\mathcal{A}, \alpha}(t) + 1$ , where the inequality holds because the shortest path from  $\alpha(s)$  to the goal in  $\mathcal{A}$  cannot be longer than the shortest path from  $\alpha(s)$  to the goal via  $\alpha(t)$ .  $\square$

Summary

## Definition (affecting transition labels)

Let  $\mathcal{T}$  be a transition system, and let  $l$  be one of its labels. We say that  $l$  **affects**  $\mathcal{T}$  if  $\mathcal{T}$  has a transition  $\langle s, l, t \rangle$  with  $s \neq t$ .

## Theorem (affecting labels vs. orthogonality)

*Let  $\mathcal{A}_1$  be an abstraction of  $\mathcal{T}$  with abstraction mapping  $\alpha_1$ . Let  $\mathcal{A}_2$  be an abstraction of  $\mathcal{T}$  with abstraction mapping  $\alpha_2$ . If no label of  $\mathcal{T}$  affects both  $\mathcal{A}_1$  and  $\mathcal{A}_2$ , then  $\alpha_1$  and  $\alpha_2$  are orthogonal.*

## Proof.

We prove goal-awareness and consistency;  
the other properties follow from these two.

Let  $\mathcal{T} = \mathcal{T}(\Pi) = \langle S, L, T, s_0, S_* \rangle$ .

Goal-awareness: For goal states  $s \in S_*$ ,

$\sum_{i=1}^n h^{\alpha_i, \alpha_i}(s) = \sum_{i=1}^n 0 = 0$  because all individual abstractions  
are goal-aware.

Summary

## Theorem (heuristic quality of refinements)

Let  $h^{\mathcal{A},\alpha}$  and  $h^{\mathcal{B},\beta}$  be abstraction heuristics for the same planning task  $\Pi$  such that  $\langle \mathcal{A}, \alpha \rangle$  is a refinement of  $\langle \mathcal{B}, \beta \rangle$ . Then  $h^{\mathcal{A},\alpha}$  dominates  $h^{\mathcal{B},\beta}$ .

In other words,  $h^{\mathcal{A},\alpha}(s) \geq h^{\mathcal{B},\beta}(s)$  for all states  $s$  of  $\Pi$ .

## Proof.

Since  $\langle \mathcal{A}, \alpha \rangle$  is a refinement of  $\langle \mathcal{B}, \beta \rangle$ , there exists a mapping  $\alpha'$  such that  $\beta = \alpha' \circ \alpha$  and  $\mathcal{B}$  is an abstraction of  $\mathcal{A}$  with abstraction mapping  $\alpha'$ .

For any state  $s$  of  $\Pi$ , we get  $h^{\mathcal{B},\beta}(s) = h_{\mathcal{B}}^*(\beta(s)) = h_{\mathcal{B}}^*(\alpha'(\alpha(s))) = h^{\mathcal{B},\alpha'}(\alpha(s)) \leq h_{\mathcal{A}}^*(\alpha(s)) = h^{\mathcal{A},\alpha}(s)$ , where the inequality holds because  $h^{\mathcal{B},\alpha'}$  is an admissible heuristic in the transition system  $\mathcal{A}$ .

Summary

## Definition (isomorphic transition systems)

Let  $\mathcal{T} = \langle S, L, T, s_0, S_\star \rangle$  and  $\mathcal{T}' = \langle S', L', T', s'_0, S'_\star \rangle$  be transition systems.

We say that  $\mathcal{T}$  is **isomorphic** to  $\mathcal{T}'$ , in symbols  $\mathcal{T} \sim \mathcal{T}'$ , if there exist bijective functions  $\varphi : S \rightarrow S'$  and  $\psi : L \rightarrow L'$  such that:

- $\varphi(s_0) = s'_0$ ,
- $s \in S_\star$  iff  $\varphi(s) \in S'_\star$ , and
- $\langle s, \ell, t \rangle \in T$  iff  $\langle \varphi(s), \psi(\ell), \varphi(t) \rangle \in T'$ .

Summary

## Definition (graph-equivalent transition systems)

Let  $\mathcal{T} = \langle S, L, T, s_0, S_\star \rangle$  and  $\mathcal{T}' = \langle S', L', T', s'_0, S'_\star \rangle$  be transition systems.

We say that  $\mathcal{T}$  is **graph-equivalent to**  $\mathcal{T}'$ , in symbols  $\mathcal{T} \stackrel{G}{\sim} \mathcal{T}'$ , if there exists a bijective function  $\varphi : S \rightarrow S'$  such that:

- $\varphi(s_0) = s'_0$ ,
- $s \in S_\star$  iff  $\varphi(s) \in S'_\star$ , and
- $\langle s, \ell, t \rangle \in T$  for some  $\ell \in L$  iff  $\langle \varphi(s), \ell', \varphi(t) \rangle \in T'$  for some  $\ell' \in L'$ .

**Note:** There is no requirement that the labels of  $\mathcal{T}$  and  $\mathcal{T}'$  correspond in any way. For example, it is permitted that all transitions of  $\mathcal{T}$  have different labels and all transitions of  $\mathcal{T}'$  have the same label.

Summary

- $(\sim)$  and  $(\overset{G}{\sim})$  are equivalence relations.
- Two isomorphic transition systems are interchangeable for all practical intents and purposes.
- Two graph-equivalent transition systems are interchangeable for most intents and purposes. In particular, their state distances are identical, so they define the same abstraction heuristic for corresponding abstraction functions.
- Isomorphism implies graph equivalence, but not vice versa.

Equivalence

Practice

Summary

In practice, there are conflicting goals for abstractions:

- we want to obtain an **informative heuristic**, but
- want to keep its **representation small**.

Abstractions have small representations if they have

- **few abstract states** and
- a **succinct encoding for  $\alpha$** .

**Practice**

Summary

One-state abstraction:  $\alpha(s) := \text{const.}$

- + very few abstract states and succinct encoding for  $\alpha$
- completely uninformative heuristic

# Counterexample: perfect abstraction

Practice

Summary

Perfect abstraction:  $\alpha(s) := h^*(s)$ .

- + perfect heuristic and usually few abstract states
- usually no succinct encoding for  $\alpha$

# Automatically deriving good abstraction heuristics

Abstraction heuristics for planning: main research problem

Automatically derive effective abstraction heuristics for planning tasks.

↪ we will study two state-of-the-art approaches in the next two chapters

**Practice**

Summary

- An **abstraction** relates a transition system  $\mathcal{T}$  (e. g. of a planning task) to another (usually smaller) transition system  $\mathcal{T}'$  via an **abstraction mapping**  $\alpha$ .
- Abstraction **preserves all important aspects** of  $\mathcal{T}$ : initial state, goal states and (labeled) transitions.
- Hence, they can be used to define **heuristics** for the original system  $\mathcal{T}$ : estimate the goal distance of  $s$  in  $\mathcal{T}$  by the optimal goal distance of  $\alpha(s)$  in  $\mathcal{T}'$ .
- Such **abstraction heuristics** are **safe**, **goal-aware**, **admissible** and **consistent**.

Abstractions:  
informally

Abstractions:  
formally

Summary

- **Strictly homomorphic abstractions** are desirable as they do not include “unnecessary” abstract goal states or transitions (which could lower heuristic values).
- Any surjection from the states of  $\mathcal{I}$  to any set induces a strictly homomorphic abstraction in a natural way.
- Multiple abstraction heuristics can be added without losing properties like admissibility if the underlying abstraction mappings are **orthogonal**.
- One sufficient condition for orthogonality is that abstractions are **affected** by disjoint sets of labels.

Abstractions:  
informally

Abstractions:  
formally

Summary

- The process of abstraction is **transitive**: an abstraction can be abstracted further to yield another abstraction.
- Based on this notion, we can define abstractions that are **coarsenings** or **refinements** of others.
- A refinement can never lead to a worse heuristic.
- Practically useful abstractions are those which give **informative heuristics**, yet have a **small representation**.
