Admissibility
Summary

- **RPG-based relaxation heuristics** seen so far,
 - either **admissible**, but **not very informative** (h_{max}),
 - or **quite informative**, but **not admissible** (h_{add} , h_{sa} , h_{FF}).
- \rightsquigarrow **no useful relaxation heuristic for optimal planning yet.**
- This chapter: **informative admissible relaxation heuristic** (h_{LM-cut}).
- h_{LM-cut} one of the most informative admissible domain-independent heuristics currently known.

Motivation

The LM-cut heuristic
Motivation
Definitions
Finding and exploiting landmarks
Admissibility
Summary

Combination of several ideas:

- **Delete relaxation**
 - Already known from Chapter 7.
 - No repeated discussion in current chapter necessary.
- **Landmarks**
 - The central concept behind h_{LM-cut} .
 - Discussed first in this chapter.
- **Cost partitioning**
 - Only relevant in the non-unit-cost setting.
 - Discussed towards the end of this chapter.

Motivation

Example

Let Π be an SAS⁺ planning task and s a state from Π .

Assume we know the following:

- In each plan starting in s , at least one of the operators o_1 and o_2 is applied.
- In each plan starting in s , at least one of the operators o_3 and o_4 is applied.
- In each plan starting in s , the operator o_5 is applied.
- In each plan starting in s , the operator o_6 is applied.
- Operators $o_1, o_2, o_3, o_4, o_5,$ and o_6 are pairwise different.

Question: Does this give us a lower bound on $h^*(s)$?

Answer: Yes! The number of **landmarks**, i.e., $h^*(s) \geq 4$.

The LM-cut heuristic

- Motivation
- Definitions
- Finding and exploiting landmarks
- Admissibility
- Summary

Motivation

- Technique for derivation of heuristic: **landmarks**.
- Question: How to compute suitable landmarks?
- For now (as long as we only consider unit-cost actions) **suitable** landmarks means **disjoint** landmarks.
Counterexample for non-disjoint landmarks: Knowing that
 - in each plan starting in s , at least one of the operators o_1 and o_2 is applied, and
 - in each plan starting in s , at least one of the operators o_2 and o_3 is applied,
 does **not** imply that $h^*(s) \geq 2$, since the one-step action sequence o_2 might be a plan for s .

The LM-cut heuristic

- Motivation
- Definitions

- Admissibility
- Summary

Landmarks

Definition (Landmark)

A **landmark** of an SAS⁺ planning task Π is a set of actions L such that **each plan** for Π contains at least one action from L . A landmark L for Π is **minimal** if no $L' \subsetneq L$ is a landmark for Π .

Note: Landmarks in this sense are also called **disjunctive action landmarks**.

Theorem

Let Π with initial state l be an SAS⁺ planning task. If there are n **disjoint** landmarks for Π , then $h(l) = n$ is an **admissible heuristic estimate** for state l .

Proof.

Obvious. □

The LM-cut heuristic

- Motivation
- Definitions
- Finding and exploiting landmarks
- Admissibility
- Summary

Landmarks

Example

$\langle A, l, \{o_1, o_2, o_3, o_4, o_5\}, \gamma \rangle$ with

$$\begin{aligned}
 A &= \{a, b, c, d, e, f, g\} & l &= \{a \mapsto 1\} \cup \{x \mapsto 0 \mid x \neq a\} \\
 o_1 &= \langle a, b \wedge c \rangle & o_2 &= \langle a, c \wedge d \rangle \\
 o_3 &= \langle a, d \wedge e \rangle & o_4 &= \langle a, e \wedge b \rangle \\
 o_5 &= \langle a, f \rangle & o_6 &= \langle b \wedge c \wedge d \wedge e \wedge f, g \rangle \\
 \gamma &= g
 \end{aligned}$$

(Minimal) landmarks:

$$\begin{aligned}
 \{o_1, o_2\} & \text{ (because of } c), & \{o_2, o_3\} & \text{ (because of } d), \\
 \{o_3, o_4\} & \text{ (because of } e), & \{o_4, o_1\} & \text{ (because of } b), \\
 \{o_5\} & \text{ (because of } f), & \{o_6\} & \text{ (because of } g)
 \end{aligned}$$

The LM-cut heuristic

- Motivation
- Definitions
- Finding and exploiting landmarks
- Admissibility
- Summary

Example (ctd.)

But at most four disjoint landmarks, e.g.,
 $\{o_1, o_2\}, \{o_3, o_4\}, \{o_5\}, \{o_6\}$.

$\rightsquigarrow h_{LM}(l) = 4$ is admissible.

Theorem

Let Π be an SAS^+ planning task, and let Π^+ be its delete relaxation. Let $L^+ = \{o^+ \mid o \in L\}$ be a landmark for Π^+ . Then L is also a landmark for Π .

Proof.

Let L^+ be a landmark for Π^+ . Then every plan π^+ for Π^+ uses some action $o^+ \in L^+$.

Let π' be some plan for Π . We need to show that π' uses some action $o \in L$. Since π' is a plan for Π , also π'^+ is a plan for Π^+ .

By assumption, π'^+ must use some action $o^+ \in L^+$. But then, π' uses action $o \in L$. \square

Theorem

Let Π be an SAS^+ planning task, and let Π^+ be its delete relaxation. Let $L^+ = \{o^+ \mid o \in L\}$ be a landmark for Π^+ . Then L is also a landmark for Π . \square

\rightsquigarrow It is sufficient to search for landmarks in the delete relaxation. This will only lead to too few discovered landmarks, not to too many.

\rightsquigarrow Admissibility of the heuristic will be preserved.

For the rest of this chapter, we assume **delete-free** planning tasks $\Pi = \Pi^+$ and search for landmarks for Π^+ , which gives us a good approximation of the **optimal delete relaxation heuristic** h^+ .

Naive approach:

- 1 Compute set $\mathcal{L} = \{L_1, \dots, L_n\}$ of **all** minimal landmarks of planning task Π .
- 2 Compute a cardinality-maximal subset $\mathcal{L}' \subseteq \mathcal{L}$ such that all $L_i, L_j \in \mathcal{L}'$, $L_i \neq L_j$, are pairwise disjoint, and return their number, $|\mathcal{L}'|$.

Drawbacks of naive approach: Both steps too complicated.

Simpler incomplete approach:

Compute set $\mathcal{L} = \{L_1, \dots, L_n\}$ of **some disjoint** minimal landmarks for Π **incrementally**.

- Compute some landmark L_1 .
- When computing L_{i+1} , only consider candidates that are disjoint from all previous landmarks L_1, \dots, L_i .
- Stop when no more such landmarks exist.

We implement the simpler approach by exploiting a relationship between landmarks and cuts in certain graphs:

- **Assumption:** STRIPS tasks with action costs 0 or 1.
- When computing landmark L_{i+1} , an action o costs zero if:
 - it is a dummy action o_s constructing the initial state from the unique initial proposition \mathbf{s} ,
 - it is a dummy action o_t constructing the unique dummy goal proposition \mathbf{t} from the actual goal propositions, or
 - it **has already been included in one of the previous landmarks** L_1, \dots, L_i , i.e., it has already been accounted for in the heuristic computation.

- To that end, in the algorithm we will present, action cost values will be iteratively decremented.
 - In the first iteration, we have action costs $c_1(o_s) = c_1(o_t) = 0$, and $c_1(o) = 1$ for all other actions o .
 - Cost functions in later iterations $i + 1$ are denoted by c_{i+1} and will differ from c_i in that costs of actions used in L_i are set to zero.

Definition (Precondition-choice function)

A **precondition-choice function (pcf)** is a function D that maps each action into one of its preconditions.
(We assume that each action has at least one precondition.)

Definition (Justification graph)

The **justification graph** for a pcf D , denoted by $G(D)$, is a directed graph whose vertices are the propositions and which has an edge (p, q) labeled with o iff the action o adds q and $D(o) = p$.

Definition (Cut)

For two nodes s and t in a justification graph, an **s-t cut** in that justification graph is a subset C of its edges such that all paths from s to t use an edge from C .

When s and t are clear, we simply call C a cut.

Theorem (Cuts correspond to landmarks)

Let C be a cut in a justification graph for an arbitrary pcf. Then the edge labels for C are a landmark. □

Definition (h_{\max} costs of atoms)

Given a fixed initial state s and an action cost function c , the h_{\max} cost of an atom a , denoted by $h_{\max}^c(a)$, is the value the RPG proposition node for atom a in the last RPG layer is labeled with after the RPG computation (with layer 0 initialized with state s and action costs given by c) has converged/stabilized.

Intuitively, $h_{\max}^c(a)$ is the cost of making a true under parallel relaxed semantics, maximizing over precondition costs. For unit-costs tasks, $h_{\max}^c(a)$ would be the index of the first RPG layer in the RPG seeded with s where a becomes true.

LM-cut Heuristic: Motivation

- In general **exponentially many pcfs**, i.e., we cannot compute all relevant landmarks.
 - The **LM-cut heuristic** is a method to compute pcfs and cuts in a **goal-directed** way.
 - Efficient partitioning of actions into cuts.
- ↪ **currently best admissible planning heuristic**

Pseudocode of LM-cut heuristic

Initialize $h = 0$ and $i = 1$.

Step 1. **Compute $h_{\max}^{c_i}(a)$ values** for every atom $a \in A$.
 Terminate if $h_{\max}^{c_i}(t) = 0$.

Step 2. **Compute pcf D_i** : Modify actions by keeping only one proposition in the precondition of each action: a proposition maximizing $h_{\max}^{c_i}$, breaking ties arbitrarily.

Step 3. **Construct justification graph G_i of D_i** : Vertices are the propositions; for each action $o = \langle p, q_1 \wedge \dots \wedge q_k \rangle$ and each $j = 1, \dots, k$, there is an edge from p to q_j with cost $c_i(o)$ and label o .

Step 4. ...

Pseudocode of LM-cut heuristic (ctd.)

The LM-cut heuristic
Motivation
Definitions
Finding and exploiting landmarks
Admissibility
Summary

- Step 4. **Construct an s-t-cut** $C_i = (V_i^0, V_i^* \cup V_i^b)$ of G_i as follows: V_i^* contains all propositions from which \mathbf{t} can be reached through a zero-cost path, V_i^0 contains all propositions reachable from \mathbf{s} without passing through some propositions in V_i^* , and V_i^b contains all remaining propositions. Clearly, $\mathbf{s} \in V_i^0$ and $\mathbf{t} \in V_i^*$.
- Step 5. **Determine disjunctive action landmark:** Let L_i be the set of labels of the edges that cross the cut C_i (i.e., lead from V_i^0 to V_i^*).
- Step 6. **Decrease action costs:** Define $c_{i+1}(o) := c_i(o)$ if $o \notin L_i$, and $c_{i+1}(o) := 0$ if $o \in L_i$.
- Step 7. **Increase heuristic value:** $h := h + 1$.
- Step 8. Set $i := i + 1$ and go to Step 1.

Example

The LM-cut heuristic

Admissibility
Summary

Adaptation/simplification of running example from Chapter 8: planning task $\langle A, I, \{o_s, o_1, o_2, o_3, o_4, o_t\}, \gamma \rangle$ with

$$A = \{\mathbf{s}, a, b, c, d, e, f, g, h, \mathbf{t}\}$$

$$I = \{\mathbf{s} \mapsto 1, a \mapsto 0, b \mapsto 0, c \mapsto 0, d \mapsto 0, e \mapsto 0, f \mapsto 0, g \mapsto 0, h \mapsto 0, \mathbf{t} \mapsto 0\}$$

$$o_s = \langle \mathbf{s}, a \wedge c \wedge d \rangle$$

$$o_1 = \langle c \wedge d, b \rangle$$

$$o_2 = \langle a \wedge b, e \rangle$$

$$o_3 = \langle a, f \rangle$$

$$o_4 = \langle f, g \wedge h \rangle$$

$$o_t = \langle e \wedge g \wedge h, \mathbf{t} \rangle$$

$$\gamma = \mathbf{t}$$

Example

The LM-cut heuristic
Motivation
Definitions
Finding and exploiting landmarks
Admissibility
Summary

- **Cheapest sequential (relaxed) plan:** $\langle o_s, o_1, o_2, o_3, o_4, o_t \rangle$ with cost $h^+(I) = 4$ (recall that o_s and o_t cost nothing).
- **Parallel (relaxed) plan witnessing $h_{\max}(I) = 2$:** $\langle \{o_s\}, \{o_1, o_3\}, \{o_2, o_4\}, \{o_t\} \rangle$.

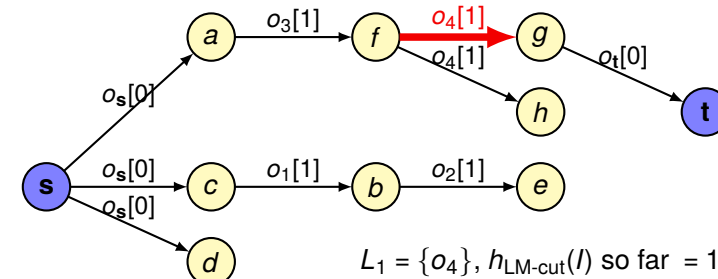

Our aim: Get closer to $h^+(I) = 4$ using $h_{\text{LM-cut}}$ than using h_{\max} .

 $o_t[0] = \langle e \wedge g \wedge h, t \rangle$

Theorem

The LM-cut heuristic never overestimates h^* , i.e., it is admissible.

Proof sketch

- From every landmark found, at least one operator has to be applied in any relaxed plan.
- Each found landmark is counted only once and there is no overlap in operators used in landmarks, i.e., the landmarks that are found are disjoint (operator costs for all operators in a “used” landmark are reset to zero).
- Therefore, we count at most as many landmarks as there are operators in a shortest relaxed plan.

- Remark: h_{LM-cut} can be generalized to planning tasks with non-unit costs.

- Instead of setting operator costs to zero, decrease costs of all operators in landmark by the minimal cost of any operator in the landmark. This effectively leads to a cost partitioning of operator costs between landmarks: An operator can be (partly) counted in more than one landmark, but the sum of the weights it is counted with will not exceed its true cost.
- Instead of incrementing heuristic value by one in each step, increase it by minimal cost of any operator in the landmark.

Then, h_{LM-cut} is still admissible. Proof via cost-partitioning argument.

Outlook: Non-unit-cost tasks

Example

Iter. 1: $D(t) = a \rightsquigarrow L_1 = \{o_2, o_3\} [4]$

- $o_1[3] = \langle s, a \wedge b \rangle$
- $o_2[4] = \langle s, a \wedge c \rangle$
- $o_3[5] = \langle s, b \wedge c \rangle$
- $o_4[0] = \langle a \wedge b \wedge c, t \rangle$

Outlook: Non-unit-cost tasks

Example

Iter. 1: $D(t) = a \rightsquigarrow L_1 = \{o_2, o_3\} [4] \rightsquigarrow h_{LM-cut}(l) := 4$

- $o_1[3] = \langle s, a \wedge b \rangle$
- $o_2[0] = \langle s, a \wedge c \rangle$
- $o_3[1] = \langle s, b \wedge c \rangle$
- $o_4[0] = \langle a \wedge b \wedge c, t \rangle$

Outlook: Non-unit-cost tasks

Example

Iter. 2: $D(\mathbf{t}) = b \rightsquigarrow L_2 = \{o_1, o_3\} [1]$

$o_1[3] = \langle \mathbf{s}, a \wedge b \rangle$
 $o_2[0] = \langle \mathbf{s}, a \wedge c \rangle$
 $o_3[1] = \langle \mathbf{s}, b \wedge c \rangle$
 $o_4[0] = \langle a \wedge b \wedge c, \mathbf{t} \rangle$

 $o_4[0] = \langle a \wedge b \wedge c, \mathbf{t} \rangle$

The LM-cut heuristic
 Motivation
 Definitions
 Finding and exploiting landmarks
 Admissibility
 Summary

Outlook: Non-unit-cost tasks

Remark: The costs of o_3 (i.e., 5) were **partitioned** as follows:

- 4 cost units were used in the cost of L_1 , and
- 1 cost unit was used in the cost of L_2 .

Without this cost partitioning, we would have only found L_1 and counted it at a cost of 4. Landmark L_2 would not have been considered, since it is **not** disjoint from L_1 .

Thus, we would have arrived at an unnecessarily low value $h_{\text{LM-cut}}(l) = 4$ instead of $h_{\text{LM-cut}}(l) = 5$.

The LM-cut heuristic
 Motivation
 Definitions
 Finding and exploiting landmarks
 Admissibility
 Summary

- **Landmarks** are sets of actions such that each plan contains at least one of these actions.
- **Cuts** in **justification graphs** are a very general method to find landmarks.
- The **LM-cut heuristic** is an efficient admissible heuristic based on landmarks and cuts.
- It combines **delete relaxation**, **landmarks**, and **cost partitioning**.
