# Parallel plans

#### Parallel plans

Plan steps Forward distances

Relaxed planning graphs

Relaxation heuristics

## Towards better relaxed plans

Why does the greedy algorithm compute low-quality plans?

It may apply many operators which are not goal-directed.

How can this problem be fixed?

- Reaching the goal of a relaxed planning task is most easily achieved with forward search.
- Analyzing relevance of an operator for achieving a goal (or subgoal) is most easily achieved with backward search.

Idea: Use a forward-backward algorithm that first finds a path to the goal greedily, then prunes it to a relevant subplan.

Parallel plans

Plan steps
Forward distance:

Relaxed planning graphs

Relaxation heuristics

How to decide which operators to apply in forward direction?

■ We avoid such a decision by applying all applicable operators simultaneously.

#### Definition (plan step)

A plan step is a set of operators  $\omega = \{\langle \chi_1, e_1 \rangle, \dots, \langle \chi_n, e_n \rangle\}.$ In the special case of all operators of  $\omega$  being relaxed, we further define:

- Plan step  $\omega$  is applicable in state s iff  $s \models \chi_i$  for all  $i \in \{1, ..., n\}.$
- The result of applying  $\omega$  to s, in symbols  $app_{\omega}(s)$ , is defined as the state s' with  $on(s') = on(s) \cup \bigcup_{i=1}^{n} [e_i]_s$ .

general semantics for plan steps \infty much later

#### Applying relaxed plan steps: examples

Parallel plans

#### Plan steps

Forward distanc

Relaxed planning graphs

Relaxation heuristics

In all cases, 
$$s = \{a \mapsto 0, b \mapsto 0, c \mapsto 1, d \mapsto 0\}.$$

$$lacksquare$$
  $\omega = \{\langle c, a \rangle, \langle \top, b \rangle\}$ 

#### Serializations

Applying a relaxed plan step to a state is related to applying the operators in the step to a state in sequence.

#### Definition (serialization)

A serialization of plan step  $\omega = \{o_1^+, \dots, o_n^+\}$  is a sequence  $o_{\pi(1)}^+, \dots, o_{\pi(n)}^+$  where  $\pi$  is a permutation of  $\{1, \dots, n\}$ .

#### Lemma (conservativeness of plan step semantics)

If  $\omega$  is a plan step applicable in a state s of a relaxed planning task, then each serialization  $o_1, \ldots, o_n$  of  $\omega$  is applicable in s and  $app_{o_1, \ldots, o_n}(s)$  dominates  $app_{\omega}(s)$ .

- Does equality hold for all/some serialization(s)?
- What if there are no conditional effects?
- What if we allowed general (unrelaxed) planning tasks?

Parallel plans

Plan steps

Relaxed planning graphs

Relaxation heuristics

#### Definition (parallel plan)

A parallel plan for a relaxed planning task  $\langle A, I, O^+, \gamma \rangle$  is a sequence of plan steps  $\omega_1, \dots, \omega_n$  of operators in  $O^+$  with:

- $\blacksquare$   $s_0 := I$
- For i = 1,...,n, step  $\omega_i$  is applicable in  $s_{i-1}$  and  $s_i := app_{\omega_i}(s_{i-1})$ .
- $\blacksquare s_n \models \gamma$

Remark: By ordering the operators within each single step arbitrarily, we obtain a (regular, non-parallel) plan.

Parallel plans Plan steps

Forward distant

Relaxed planning graphs

Relaxation heuristics

#### Forward states, plan steps and sets

- Idea: In the forward phase of the heuristic computation,
  - apply plan step with all operators applicable initially,
  - 2 apply plan step with all operators applicable then,
  - and so on.

#### Definition (forward state/plan step/set)

Let  $\Pi^+ = \langle A, I, O^+, \gamma \rangle$  be a relaxed planning task.

The *n*-th forward state, in symbols  $s_n^F$  ( $n \in \mathbb{N}_0$ ), the *n*-th forward plan step, in symbols  $\omega_n^F$  ( $n \in \mathbb{N}_1$ ), and the *n*-th forward set, in symbols  $S_n^F$  ( $n \in \mathbb{N}_0$ ), are defined as:

$$s_0^F := I$$

$$lacksquare$$
  $\omega_n^{\mathsf{F}} := \{o \in O^+ \mid o \text{ applicable in } s_{n-1}^{\mathsf{F}} \} \text{ for all } n \in \mathbb{N}_1$ 

$$\blacksquare$$
  $s_n^{\mathsf{F}} := app_{\omega_n^{\mathsf{F}}}(s_{n-1}^{\mathsf{F}}) \text{ for all } n \in \mathbb{N}_1$ 

$$S_n^{\mathsf{F}} := on(s_n^{\mathsf{F}}) \text{ for all } n \in \mathbb{N}_0$$

Plan steps

#### Forward distances

Relaxed planning graphs

Relaxation heuristics

#### Definition (parallel forward distance)

The parallel forward distance of a relaxed planning task  $\langle A, I, O^+, \gamma \rangle$  is the lowest number  $n \in \mathbb{N}_0$  such that  $s_n^\mathsf{F} \models \gamma$ , or  $\infty$  if no forward state satisfies  $\gamma$ .

Remark: The parallel forward distance can be computed in polynomial time. (How?)

#### Definition (max heuristic $h_{max}$ )

Let  $\Pi = \langle A, I, O, \gamma \rangle$  be a planning task in positive normal form, and let *s* be a state of  $\Pi$ .

The max heuristic estimate for s,  $h_{\text{max}}(s)$ , is the parallel forward distance of the relaxed planning task  $\langle A, s, O^+, \gamma \rangle$ .

Remark:  $h_{max}$  is safe, goal-aware, admissible and consistent. (Whv?)

Parallel plans Plan steps

Forward distances

Relaxed planning graphs

Relaxation heuristics

#### So far, so good...

Paral

- We have seen how systematic computation of forward states leads to an admissible heuristic estimate
- However, this estimate is very coarse.
- To improve it, we need to include backward propagation of information.

For this purpose, we use so-called relaxed planning graphs.

plans

# Relaxed planning graphs

Paralle plans

Relaxed planning graphs

Construction
Truth values

Relaxation

#### Definition (AND/OR dag)

An AND/OR dag  $\langle V, A, type \rangle$  is a directed acyclic graph  $\langle V, A \rangle$ with a label function *type* :  $V \rightarrow \{\land, \lor\}$  partitioning nodes into AND nodes  $(type(v) = \land)$  and OR nodes  $(type(v) = \lor)$ .

Note: AND nodes drawn as squares, OR nodes as circles.

#### Definition (truth values in AND/OR dags)

Let  $G = \langle V, A, type \rangle$  be an AND/OR dag, and let  $u \in V$  be a node with successor set  $\{v_1, \ldots, v_k\} \subseteq V$ .

The (truth) value of u, val(u), is inductively defined as:

- If  $type(u) = \wedge$ , then  $val(u) = val(v_1) \wedge \cdots \wedge val(v_k)$ .
- If  $type(u) = \vee$ , then  $val(u) = val(v_1) \vee \cdots \vee val(v_k)$ .

Introduction

#### Relaxed planning graphs

Let  $\Pi^+$  be a relaxed planning task, and let  $k \in \mathbb{N}_0$ .

The relaxed planning graph of  $\Pi^+$  for depth k, in symbols  $RPG_k(\Pi^+)$ , is an AND/OR dag that encodes

- which propositions can be made true in *k* plan steps, and
- how they can be made true.

Its construction is a bit involved, so we present it in stages.

Paralle plans

Relaxed planning graphs

Construction

Iruth values

heuristics

#### Running example

As a running example, consider the relaxed planning task  $\langle A, I, \{o_1, o_2, o_3, o_4\}, \gamma \rangle$  with

$$A = \{a,b,c,d,e,f,g,h\}$$

$$I = \{a \mapsto 1,b \mapsto 0,c \mapsto 1,d \mapsto 1,$$

$$e \mapsto 0,f \mapsto 0,g \mapsto 0,h \mapsto 0\}$$

$$o_1 = \langle b \lor (c \land d),b \land ((a \land b) \rhd e) \rangle$$

$$o_2 = \langle \top,f \rangle$$

$$o_3 = \langle f,g \rangle$$

$$o_4 = \langle f,h \rangle$$

$$\gamma = e \land (g \land h)$$

$$S_{3}^{F} = S_{2}^{F} \text{ etc.}$$

Parallel plans

Relaxed planning graphs
Introduction

Construction Truth values

Polovotio

heuristics Summary

#### Components of relaxed planning graphs

A relaxed planning graph consists of four kinds of components:

- Proposition nodes represent the truth value of propositions after applying a certain number of plan steps.
- Idle arcs represent the fact that state variables, once true, remain true.
- Operator subgraphs represent the possibility and effect of applying a given operator in a given plan step.
- The goal subgraph represents the truth value of the goal condition after k plan steps.

Truth values

Let  $\Pi^+ = \langle A, I, O^+, \gamma \rangle$  be a relaxed planning task, let  $k \in \mathbb{N}_0$ .

For each  $i \in \{0,...,k\}$ ,  $RPG_k(\Pi^+)$  contains one proposition layer which consists of:

■ a proposition node  $a^i$  for each state variable  $a \in A$ .

Node  $a^i$  is an AND node if i = 0 and  $I \models a$ . Otherwise, it is an OR node.

#### Relaxed planning graph: idle arcs

Paralle

Relaxed

Introduction Construction

Truth values

heuristics

Summary

For each proposition node  $a^i$  with  $i \in \{1, ..., k\}$ ,  $RPG_k(\Pi^+)$  contains an arc from  $a^i$  to  $a^{i-1}$  (idle arcs).

Intuition: If a state variable is true in step i, one of the possible reasons is that it was already previously true.

#### Relaxed planning graph: operator subgraphs

For each  $i \in \{1,...,k\}$  and each operator  $o^+ = \langle \chi, e^+ \rangle \in O^+$ ,  $RPG_k(\Pi^+)$  contains a subgraph called an operator subgraph with the following parts:

- one formula node  $n_{\varphi}^{i}$  for each formula  $\varphi$  which is a subformula of  $\chi$  or of some effect condition in  $e^{+}$ :
  - If  $\varphi = a$  for some atom a,  $n_{\varphi}^{i}$  is the proposition node  $a^{i-1}$ .
  - If  $\varphi = \top$ ,  $n_{\varphi}^{i}$  is a new AND node without outgoing arcs.
  - If  $\varphi = \bot$ ,  $n_{\varphi}^{i}$  is a new OR node without outgoing arcs.
  - If  $\varphi = (\varphi' \wedge \varphi'')$ ,  $n_{\varphi}^i$  is a new AND node with outgoing arcs to  $n_{\varphi'}^i$  and  $n_{\varphi''}^i$ .
  - If  $\varphi = (\varphi' \vee \varphi'')$ ,  $n_{\varphi}^i$  is a new OR node with outgoing arcs to  $n_{\varphi'}^i$  and  $n_{\varphi''}^i$ .

Parallel plans

Relaxed planning graphs

Construction Truth values

neuristics

#### Relaxed planning graph: operator subgraphs

For each  $i \in \{1, ..., k\}$  and each operator  $o^+ = \langle \chi, e^+ \rangle \in O^+$ ,  $RPG_k(\Pi^+)$  contains a subgraph called an operator subgraph with the following parts:

- for each conditional effect  $(\chi' \triangleright a)$  in  $e^+$ , an effect node  $o^i_{\chi'}$  (an AND node) with outgoing arcs to the precondition formula node  $n^i_{\chi}$  and effect condition formula node  $n^i_{\chi'}$ , and incoming arc from proposition node  $a^i$ 
  - unconditional effects a (effects which are not part of a conditional effect) are treated the same, except that there is no arc to an effect condition formula node
  - effects with identical condition (including groups of unconditional effects) share the same effect node
  - $\blacksquare$  the effect node for unconditional effects is denoted by  $o^i$

## Relaxed planning graph: goal subgraph

 $RPG_{k}(\Pi^{+})$  contains a subgraph called a goal subgraph with the following parts:

- one formula node  $n_{\varphi}^{k}$  for each formula  $\varphi$  which is a subformula of  $\gamma$ :
  - If  $\varphi = a$  for some atom a,  $n_{\varphi}^{k}$  is the proposition node  $a^{i}$ .
  - If  $\varphi = \top$ ,  $n_{\varphi}^{k}$  is a new AND node without outgoing arcs.
  - If  $\varphi = \bot$ ,  $n_{\varphi}^{k}$  is a new OR node without outgoing arcs.
  - If  $\varphi = (\varphi' \wedge \varphi'')$ ,  $n_{\varphi}^k$  is a new AND node with outgoing arcs to  $n_{\varphi'}^k$  and  $n_{\varphi''}^k$ .
  - If  $\varphi = (\varphi' \vee \varphi'')$ ,  $n_{\varphi}^k$  is a new OR node with outgoing arcs to  $n_{\varphi'}^k$  and  $n_{\varphi''}^k$ .

The node  $n_{\gamma}^{k}$  is called the goal node.

### Theorem (relaxed planning graph truth values)

Let  $\Pi^+ = \langle A, I, O^+, \gamma \rangle$  be a relaxed planning task. Then the truth values of the nodes of its depth-k relaxed planning graph  $RPG_k(\Pi^+)$  relate to the forward sets and forward plan steps of  $\Pi^+$  as follows:

- Proposition nodes: For all  $a \in A$  and  $i \in \{0,...,k\}$ ,  $val(a^i) = 1$  iff  $a \in S_i^F$ .
- (Unconditional) effect nodes: For all  $o \in O^+$  and  $i \in \{1,...,k\}$ ,  $val(o^i) = 1$  iff  $o \in \omega_i^F$ .
- Goal nodes:  $val(n_{\gamma}^{k}) = 1$  iff the parallel forward distance of  $\Pi^{+}$  is at most k.

(We omit the straight-forward proof.)

Relaxation heuristics

- Only one effect node per operator: STRIPS does not have conditional effects.
  - Because each operator has only one effect node, effect nodes are called operator nodes in relaxed planning graphs for STRIPS.
- No goal nodes: The test whether all goals are reached is done by the algorithm that evaluates the AND/OR dag.
- No formula nodes: Operator nodes are directly connected to their preconditions.
- → Relaxed planning graphs for STRIPS are layered digraphs and only have proposition and operator nodes.

# Computing parallel forward distances from RPGs

So far, relaxed planning graphs offer us a way to compute parallel forward distances:

### Parallel forward distances from relaxed planning graphs

```
def parallel-forward-distance(\Pi^+):

Let A be the set of state variables of \Pi^+.

for k \in \{0,1,2,\dots\}:

rpg := RPG_k(\Pi^+)

Evaluate truth values for rpg.

if goal node of rpg has value 1:

return k

else if k = |A|:

return \infty
```

planning graphs

heuristics

Generic template

n<sub>max</sub> h<sub>add</sub>

n<sub>sa</sub> Incrementa

computation her

Comparison practice

## Remarks on the algorithm

- The relaxed planning graph for depth  $k \ge 1$  can be built incrementally from the one for depth k 1:
  - Add new layer k.
  - Move goal subgraph from layer k-1 to layer k.
- Similarly, all truth values up to layer k-1 can be reused.
- Thus, overall computation with maximal depth m requires time  $O(\|RPG_m(\Pi^+)\|) = O((m+1) \cdot \|\Pi^+\|)$ .
- This is not a very efficient way of computing parallel forward distances (and wouldn't be used in practice).
- However, it allows computing additional information for the relaxed planning graph nodes along the way, which can be used for heuristic estimates.

## Concrete examples for the generic heuristic

Many planning heuristics fit the generic template:

- additive heuristic h<sub>add</sub> (Bonet, Loerincs & Geffner, 1997)
- max heuristic h<sub>max</sub> (Bonet & Geffner, 1999)
- FF heuristic *h*<sub>FF</sub> (Hoffmann & Nebel, 2001)
- cost-sharing heuristic h<sub>cs</sub> (Mirkis & Domshlak, 2007)
  - not covered in this course
- set-additive heuristic *h*<sub>sa</sub> (Keyder & Geffner, 2008)

#### Remarks:

- For all these heuristics, equivalent definitions that don't refer to relaxed planning graphs are possible.
- Historically, such equivalent definitions have mostly been used for  $h_{\text{max}}$ ,  $h_{\text{add}}$  and  $h_{\text{sa}}$ .
- For those heuristics, the most efficient implementations do not use relaxed planning graphs explicitly.

Paralle plans

Relaxed planning graphs

Relaxation heuristics

#### Generic template

h<sub>max</sub> h<sub>add</sub>

h<sub>sa</sub>

Incremental computation

Comparison 8 practice

### Forward cost heuristics

- The simplest relaxed planning graph heuristics are forward cost heuristics.
- Examples: h<sub>max</sub>, h<sub>add</sub>
- Here, node annotations are cost values (natural numbers).
- The cost of a node estimates how expensive (in terms of required operators) it is to make this node true.

Paralle plans

Relaxed planning graphs

heuristics

#### Generic template

h<sub>max</sub> h<sub>add</sub>

 $h_{\mathrm{sa}}$ 

Incremental computation

Comparison & practice

#### Forward cost heuristics

### Computing annotations:

- Propagate cost values bottom-up using a combination rules for OR nodes and for AND nodes.
- At effect nodes, add 1 after applying combination rule.

#### Termination criterion:

stability: terminate if cost for proposition node  $a^k$  equals cost for  $a^{k-1}$  for all true propositions a in layer k (and true propositions in layers k and k-1 are the same)

#### Heuristic value:

- The heuristic value is the cost of the goal node.
- Different forward cost heuristics only differ in their choice of combination rules.

Parallel plans

Relaxed planning graphs

Relaxation heuristics

#### Generic template

h<sub>max</sub> h<sub>add</sub>

Incremental

computation

Comparison practice

# FREIB

#### Forward cost heuristics: max heuristic $h_{\text{max}}$

#### Combination rule for AND nodes:

 $cost(u) = \max(\{cost(v_1), \dots, cost(v_k)\})$  (with max( $\emptyset$ ) := 0)

#### Combination rule for OR nodes:

 $oldsymbol{o}$  cost(u) = min({cost(v<sub>1</sub>),...,cost(v<sub>k</sub>)})

In both cases,  $\{v_1, \dots, v_k\}$  is the set of true successors of u.

#### Intuition:

- AND rule: If we have to achieve several conditions, estimate this by the most expensive cost.
- OR rule: If we have a choice how to achieve a condition, pick the cheapest possibility.

# Relaxed planning graphs

## Relaxation heuristics

Generic template

### h<sub>ma</sub>

n<sub>add</sub>

Incremental computation

Comparison 8 practice

- The definition of  $h_{\text{max}}$  as a forward cost heuristic is equivalent to our earlier definition in this chapter.
- Unlike the earlier definition, it generalizes to an extension where every operator has an associated non-negative cost (rather than all operators having cost 1).
- In the case without costs (and only then), it is easy to prove that the goal node has the same cost in all graphs  $RPG_k(\Pi^+)$  where it is true. (Namely, the cost is equal to the lowest value of k for which the goal node is true.)
- We can thus terminate the computation as soon as the goal becomes true, without waiting for stability.
- The same is not true for other forward-propagating heuristics ( $h_{add}$ ,  $h_{cs}$ ,  $h_{sa}$ ).

Comparison 8 practice

- It is important to test for stability in computing  $h_{add}$ ! (The reason for this is that, unlike  $h_{max}$ , cost values of true propositions can decrease from layer to layer.)
- Stability is achieved after layer |A| in the worst case.
- h<sub>add</sub> is safe and goal-aware.
- Unlike  $h_{\text{max}}$ ,  $h_{\text{add}}$  is a very informative heuristic in many planning domains.
- The price for this is that it is not admissible (and hence also not consistent), so not suitable for optimal planning.
- In fact, it almost always overestimates the h<sup>+</sup> value because it does not take positive interactions into account.

h

h<sub>add</sub>

h<sub>sa</sub> Incrementa

computation

Comparison 8 practice

- We now discuss a refinement of the additive heuristic called the set-additive heuristic  $h_{sa}$ .
- The set-additive heuristic addresses the problem that h<sub>add</sub> does not take positive interactions into account.
- Like  $h_{\text{max}}$  and  $h_{\text{add}}$ ,  $h_{\text{sa}}$  is calculated through forward propagation of node annotations.
- However, the node annotations are not cost values, but sets of operators (kind of).
- The idea is that by taking set unions instead of adding costs, operators needed only once are counted only once.

Disclaimer: There are some quite subtle differences between the  $h_{\rm sa}$  heuristic as we describe it here and the "real" heuristic of Keyder & Geffner. We do not want to discuss this in detail, but please note that such differences exist.

Generic tempiate h<sub>max</sub>

h<sub>sa</sub>

Incremental

h<sub>FF</sub> Comparison 8

- The original h<sub>sa</sub> heuristic as described in the literature is defined for STRIPS tasks and propagates sets of operators.
- This is fine because in relaxed STRIPS tasks, each operator need only be applied once.
- The same is not true in general: in our running example, operator  $o_1$  must be applied twice in the relaxed plan.
- In general, it only makes sense to apply an operator again in a relaxed planning task if a previously unsatisfied effect condition has been made true.
- For this reason, we keep track of operator/effect condition pairs rather than just plain operators.

### The set-additive heuristic $h_{sa}$

### Computing annotations:

Annotations are sets of operator/effect condition pairs, computed bottom-up.

Combination rule for AND nodes:

■  $ann(u) = ann(v_1) \cup \cdots \cup ann(v_k)$  (with  $\bigcup (\emptyset) := \emptyset$ )

Combination rule for OR nodes:

■  $ann(u) = ann(v_i)$  for some  $v_i$  minimizing  $|ann(v_i)|$  In case of several minimizers, use any tie-breaking rule.

In both cases,  $\{v_1, \ldots, v_k\}$  is the set of true successors of u. At effect nodes, add the corresponding operator/effect condition pair to the set after applying combination rule.

- The same remarks for stability as for  $h_{add}$  apply.
- Like *h*<sub>add</sub>, *h*<sub>sa</sub> is safe and goal-aware, but neither admissible nor consistent.
- $h_{sa}$  is generally better informed than  $h_{add}$ , but significantly more expensive to compute.
- The *h*<sub>sa</sub> value depends on the tie-breaking rule used, so *h*<sub>sa</sub> is not well-defined without specifying the tie-breaking rule.
- The operators contained in the goal node annotation, suitably ordered, define a relaxed plan for the task.
  - Operators mentioned several times in the annotation must be added as many times in the relaxed plan.

# Incremental computation of forward heuristics

One nice property of forward-propagating heuristics is that they allow incremental computation:

- when evaluating several states in sequence which only differ in a few state variables, can
  - start computation from previous results and
  - keep track only of what needs to be recomputed
- typical use case: depth-first style searches (e.g., IDA\*)
- rarely exploited in practice

n<sub>max</sub> h<sub>add</sub>

Incremental computation

Comparison 8

- h<sub>sa</sub> is more expensive to compute than the other forward propagating heuristics because we must propagate sets.
- It is possible to get the same advantage over  $h_{add}$  combined with efficient propagation.
- Key idea of h<sub>FF</sub>: perform a backward propagation that selects a sufficient subset of nodes to make the goal true (called a solution graph in AND/OR dag literature).
- The resulting heuristic is almost as informative as  $h_{sa}$ , yet computable as quickly as  $h_{add}$ .

Note: Our presentation inverts the historical order. The set-additive heuristic was defined after the FF heuristic (sacrificing speed for even higher informativeness). Parallel plans

### The FF heuristic hFF

#### Computing annotations:

■ Annotations are Boolean values, computed top-down.

A node is marked when its annotation is set to 1 and unmarked if it is set to 0. Initially, the goal node is marked, and all other nodes are unmarked.

We say that a true AND node is justified if all its true successors are marked, and that a true OR node is justified if at least one of its true successors is marked.

### The FF heuristic $h_{FF}$ (ctd.)

#### Computing annotations:

**...** 

Apply these rules until all marked nodes are justified:

- Mark all true successors of a marked unjustified AND node
- Mark the true successor of a marked unjustified OR node with only one true successor.
- Mark a true successor of a marked unjustified OR node connected via an idle arc.
- 4 Mark any true successor of a marked unjustified OR node.

The rules are given in priority order: earlier rules are preferred if applicable.

- Like  $h_{\text{add}}$  and  $h_{\text{sa}}$ ,  $h_{\text{FF}}$  is safe and goal-aware, but neither admissible nor consistent.
- Its informativeness can be expected to be slightly worse than for  $h_{sa}$ , but is usually not far off.
- Unlike  $h_{sa}$ ,  $h_{FF}$  can be computed in linear time.
- Similar to  $h_{sa}$ , the operators corresponding to the marked operator/effect condition pairs define a relaxed plan.
- Similar to h<sub>sa</sub>, the h<sub>FF</sub> value depends on tie-breaking when the marking rules allow several possible choices, so h<sub>FF</sub> is not well-defined without specifying the tie-breaking rule.
  - The implementation in FF uses additional rules of thumb to try to reduce the size of the generated relaxed plan.

# FRE

#### Theorem (relationship between relaxation heuristics)

Let s be a state of planning task  $\langle A, I, O, \gamma \rangle$ . Then:

- $h_{max}(s) \le h^{+}(s) \le h^{*}(s)$
- $h_{max}(s) \le h^+(s) \le h_{sa}(s) \le h_{add}(s)$
- $\blacksquare h_{max}(s) \leq h^+(s) \leq h_{FF}(s) \leq h_{add}(s)$
- $\blacksquare$   $h^*$ ,  $h_{FF}$  and  $h_{sa}$  are pairwise incomparable
- $\blacksquare$   $h^*$  and  $h_{add}$  are incomparable

Moreover,  $h^+$ ,  $h_{max}$ ,  $h_{add}$ ,  $h_{sa}$  and  $h_{FF}$  assign  $\infty$  to the same set of states.

Note: For inadmissible heuristics, dominance is in general neither desirable nor undesirable. For relaxation heuristics, the objective is usually to get as close to  $h^+$  as possible.

UNI FREIB

### Example (FF)

FF (Hoffmann & Nebel) won the 2nd International Planning Competition (IPC-2000).

#### Key ideas:

- enforced hill-climbing search using her
- helpful action pruning: in each search node, only consider successors from operators that add one of the atoms marked in proposition layer 1
- goal ordering: in certain cases, FF recognizes and exploits that certain subgoals should be solved one after the other

If main search fails, FF performs greedy best-first search using  $h_{\text{FF}}$  without helpful action pruning or goal ordering.

Relaxation heuristics

Generic template

h<sub>add</sub>

h<sub>sa</sub>

computation

Comparison & practice

- Relaxed planning graphs are AND/OR dags. They encode which propositions can be made true in Π<sup>+</sup> and how.
  - Closely related to forward sets and forward plan steps, based on the notion of parallel relaxed plans.
  - They can be constructed and evaluated efficiently, in time  $O((m+1)\|\Pi^+\|)$  for planning task  $\Pi$  and depth m.
- By annotating RPG nodes with appropriate information, we can compute many useful heuristics.
- Examples: max heuristic h<sub>max</sub>, additive heuristic h<sub>add</sub>, set-additive heuristic h<sub>sa</sub> and FF heuristic h<sub>FF</sub>
  - Of these, only  $h_{max}$  admissible (but not very accurate).
  - The others are much more informative. The set-additive heuristic is the most sophisticated one.
  - The FF heuristic is often similarly informative. It offers a good trade-off between accuracy and computation time.
