#### Motivation

Background

Complexity of planning

More complexity results

Summary

## Motivation

#### Motivation

Background

Complexity of planning

More complexity results

- We have seen that planning can be done in time polynomial in the size of the transition system.
- However, we have not seen algorithms which are polynomial in the input size (size of the task description).
- What is the precise computational complexity of the planning problem?

## Why computational complexity?

# UNI

- understand the problem better
- know what is not possible
- get a licence for using heuristic search methods (or other methods to solve NP-hard problems)
- find interesting subproblems that are easier to solve
- distinguish essential features from syntactic sugar
  - Is STRIPS planning easier than general planning?
  - Is planning for FDR tasks harder than for propositional tasks?

Summary

## Background

## Nondeterministic Turing machines

#### Definition (nondeterministic Turing machine)

A nondeterministic Turing machine (NTM) is a 6-tuple  $\langle \Sigma, \Box, Q, q_0, q_Y, \delta \rangle$  with the following components:

- input alphabet  $\Sigma$  and blank symbol  $\square \notin \Sigma$ 
  - alphabets always nonempty and finite
  - tape alphabet  $\Sigma_{\square} = \Sigma \cup \{\square\}$
- finite set Q of internal states with initial state  $q_0 \in Q$  and accepting state  $q_Y \in Q$ 
  - nonterminal states  $Q' := Q \setminus \{q_Y\}$
- transition relation  $\delta \subseteq (Q' \times \Sigma_{\square}) \times (Q \times \Sigma_{\square} \times \{-1, +1\})$

Motivation

Complexity of planning

More complexity results

## **Deterministic Turing machines**

## Definition (deterministic Turing machine)

A deterministic Turing machine (DTM) is an NTM where the transition relation is functional, i. e., for all  $\langle q,a\rangle\in Q'\times \Sigma_\square$ , there is exactly one triple  $\langle q',a',\Delta\rangle$  with  $\langle\langle q,a\rangle,\langle q',a',\Delta\rangle\rangle\in\delta$ .

Notation: We write  $\delta(q,a)$  for the unique triple  $\langle q',a',\Delta\rangle$  such that  $\langle \langle q,a\rangle, \langle q',a',\Delta\rangle\rangle \in \delta$ .

results

Summary

#### **Definition** (Configuration)

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be an NTM.

A configuration of M is a triple  $\langle w, q, x \rangle \in \Sigma_{\square}^* \times Q \times \Sigma_{\square}^*$ .

- w: tape contents before tape head
- q: current state
- x: tape contents after and including tape head

## Turing machine transitions

## UNI FREIBURG

### Definition (yields relation)

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be an NTM.

A configuration c of M yields a configuration c' of M, in symbols  $c \vdash c'$ , as defined by the following rules, where  $a, a', b \in \Sigma_{\square}$ ,  $w, x \in \Sigma_{\square}^*$ ,  $q, q' \in Q$  and  $\langle \langle q, a \rangle, \langle q', a', \Delta \rangle \rangle \in \delta$ :

$$\langle w, q, ax \rangle \vdash \langle wa', q', x \rangle \qquad \text{if } \Delta = +1, |x| \ge 1$$

$$\langle w, q, a \rangle \vdash \langle wa', q', \Box \rangle \qquad \text{if } \Delta = +1$$

$$\langle wb, q, ax \rangle \vdash \langle w, q', ba'x \rangle \qquad \text{if } \Delta = -1$$

$$\langle \varepsilon, q, ax \rangle \vdash \langle \varepsilon, q', \Box a'x \rangle \qquad \text{if } \Delta = -1$$

## Accepting configurations

# FREIBUR

### Definition (accepting configuration, time)

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be an NTM, let  $c = \langle w, q, x \rangle$  be a configuration of M, and let  $n \in \mathbb{N}_0$ .

- If  $q = q_Y$ , M accepts c in time n.
- If  $q \neq q_Y$  and M accepts some c' with  $c \vdash c'$  in time n, then M accepts c in time n + 1.

## Definition (accepting configuration, space)

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be an NTM, let  $c = \langle w, q, x \rangle$  be a configuration of M, and let  $n \in \mathbb{N}_0$ .

- If  $q = q_Y$  and  $|w| + |x| \le n$ , M accepts c in space n.
- If  $q \neq q_Y$  and M accepts some c' with  $c \vdash c'$  in space n, then M accepts c in space n.

## Accepting words and languages

## UNI FREIBURG

## Definition (accepting words)

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be an NTM.

*M* accepts the word  $w \in \Sigma^*$  in time (space)  $n \in \mathbb{N}_0$  iff *M* accepts  $\langle \varepsilon, q_0, w \rangle$  in time (space) n.

■ Special case: M accepts  $\varepsilon$  in time (space)  $n \in \mathbb{N}_0$  iff M accepts  $\langle \varepsilon, q_0, \square \rangle$  in time (space) n.

## Definition (accepting languages)

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be an NTM, and let  $f : \mathbb{N}_0 \to \mathbb{N}_0$ .

*M* accepts the language  $L \subseteq \Sigma^*$  in time (space) *f* 

iff M accepts each word  $w \in L$  in time (space) f(|w|),

and M does not accept any word  $w \notin L$  (in any time/space).

Summarv

## Time and space complexity classes

FREIBUR

#### Definition (DTIME, NTIME, DSPACE, NSPACE)

Let  $f: \mathbb{N}_0 \to \mathbb{N}_0$ .

Complexity class  $\overline{\mathsf{DTIME}}(f)$  contains all languages accepted in time O(f) by some DTM.

Complexity class  $\overline{\text{NTIME}(f)}$  contains all languages accepted in time O(f) by some NTM.

Complexity class DSPACE(f) contains all languages accepted in space O(f) by some DTM.

Complexity class NSPACE(f) contains all languages accepted in space O(f) by some NTM.

## Polynomial complexity class relationships

UNI FREIBUR

### Theorem (complexity class hierarchy)

 $P \subseteq NP \subseteq PSPACE = NPSPACE$ 

#### Proof.

 $P \subseteq NP$  and  $PSPACE \subseteq NPSPACE$  is obvious because deterministic Turing machines are a special case of nondeterministic ones.

 $NP \subseteq NPSPACE$  holds because a Turing machine can only visit polynomially many tape cells within polynomial time.

PSPACE = NPSPACE is a special case of a classical result known as Savitch's theorem (Savitch 1970).

Motivation

Background

Complexity classes

of planning

complexity

### Savitch's theorem

## UNI FREIBL

#### **Theorem**

For all  $f \in \Omega(\log(n))$ : NSPACE $(f) \subseteq DSPACE(f^2)$ .

#### Proof sketch.

Let C be the set of all configurations with  $|C| = |Q| \cdot f(n) \cdot |\Sigma + 1|^{f(n)}$  and for each  $c \in C$  we have |c| = f(n). Then the following function checks whether a configuration c' is reachable from c by calling it with **k\_path(**c, c', |V|**)** using only  $f(n)^2$  space.

```
def k_path(s,t,k):

if k=0: return s=t

if k=1: return s=t or s\vdash t

for u in C:

if k_path(s,u,\lfloor (k/2)\rfloor) and k_path(u,t,\lceil (k/2)\rceil):

return true
```

## The propositional planning problem

FREIBL

## Definition (plan existence)

The propositional plan existence problem (PLANEX) is the following decision problem:

GIVEN: Planning task Π

QUESTION: Is there a plan for  $\Pi$ ?

→ decision problem analogue of satisficing planning

#### Definition (bounded plan existence)

The propositional bounded plan existence problem (PLANLEN) is the following decision problem:

GIVEN: Planning task  $\Pi$ , length bound  $K \in \mathbb{N}_0$ QUESTION: Is there a plan for  $\Pi$  of length at most K?

→ decision problem analogue of optimal planning

Motivation

of planning (Bounded) plan existence

PSPACE-

More complexity results

## Plan existence vs. bounded plan existence

UNI FREIBURG

Theorem (reduction from PLANEx to PLANLEN)

 $PLANEx \leq_{\rho} PLANLEN$ 

#### Proof.

A propositional planning task with n state variables has a plan iff it has a plan of length at most  $2^n - 1$ .

 $\leadsto$  map instance  $\Pi$  of PlanEx to instance  $\langle \Pi, 2^n - 1 \rangle$  of PlanLen, where n is the number of n state variables of  $\Pi$ 

→ polynomial reduction

Summary

### Idea: generic reduction

- For an arbitrary fixed DTM M with space bound polynomial p and input w, generate planning task which is solvable iff M accepts w in space p(|w|).
- For simplicity, restrict to TMs which never move to the left of the initial head position (no loss of generality).

#### Reduction: state variables

7 7 7

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be the fixed DTM and let p be its space-bound polynomial.

Given input  $w_1 ... w_n$ , define relevant tape positions  $X := \{1, ..., p(n)\}.$ 

#### State variables

- state<sub>q</sub> for all  $q \in Q$
- head<sub>i</sub> for all  $i \in X \cup \{0, p(n) + 1\}$
- content<sub>i,a</sub> for all  $i \in X$ ,  $a \in \Sigma_{\square}$
- → allows encoding a Turing machine configuration

Motivation

Background

of planning (Bounded) plan

PSPACE-

completeness

### Reduction: initial state

FREBL -

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be the fixed DTM and let p be its space-bound polynomial.

Given input  $w_1 ... w_n$ , define relevant tape positions  $X := \{1, ..., p(n)\}.$ 

#### Initial state

Initially true:

- state<sub>q₀</sub>
- head<sub>1</sub>
- $\blacksquare$  content<sub> $i,w_i$ </sub> for all  $i \in \{1,...,n\}$ 
  - lacksquare content $_{i,\square}$  for all  $i\in X\setminus\{1,\ldots,n\}$

Initially false:

all others

Background

(Bounded) pla existence

PSPACEcompleteness

More complexity results

## Reduction: operators

JNI REIBURG

Let  $M = \langle \Sigma, \square, Q, q_0, q_Y, \delta \rangle$  be the fixed DTM and let p be its space-bound polynomial.

Given input  $w_1 ... w_n$ , define relevant tape positions  $X := \{1, ..., p(n)\}.$ 

### **Operators**

One operator for each transition rule  $\delta(q, a) = \langle q', a', \Delta \rangle$  and each cell position  $i \in X$ :

- precondition:  $state_q \land head_i \land content_{i,a}$
- effect:  $\neg$ state<sub>q</sub>  $\land \neg$ head<sub>i</sub>  $\land \neg$ content<sub>i,a</sub>  $\land$  state<sub>q'</sub>  $\land$  head<sub>i+\Delta</sub>  $\land$  content<sub>i,a'</sub>
  - If q = q' and/or a = a', omit the effects on state<sub>q</sub> and/or content<sub>i,a</sub>, to avoid consistency condition issues.

# PSPACE-completeness for STRIPS plan existence

FREIBUR

Theorem (PSPACE-completeness; Bylander, 1994)

PLANEX and PLANLEN are PSPACE-complete.

This is true even when restricting to STRIPS tasks.

#### Proof.

Membership for PlanLen was already shown.

Hardness for PLANEx follows because we just presented a polynomial reduction from an arbitrary problem in PSPACE to PLANEx. (Note that the reduction only generates STRIPS tasks.)

Membership for PlanEx and hardness for PlanLen follows from the polynomial reduction from PlanEx to PlanLen.

Summary

In addition to the basic complexity result presented in this chapter, there are many special cases, generalizations, variations and related problems studied in the literature:

- different planning formalisms
  - e. g., finite-domain representation, nondeterministic effects, partial observability, schematic operators, numerical state variables, state-dependent action costs
- syntactic restrictions of planning tasks
  - e.g., without preconditions, without conjunctive effects, STRIPS without delete effects
- semantic restrictions of planning task
  - e. g., restricting to certain classes of causal graphs
- particular planning domains
  - e.g., Blocksworld, Logistics, FreeCell

# Complexity results for different planning formalisms

NI REIBURG

#### Some results for different planning formalisms:

- FDR tasks:
  - same complexity as for propositional tasks ("folklore")
  - also true for the SAS<sup>+</sup> special case
- nondeterministic effects:
  - fully observable: EXP-complete (Littman, 1997)
  - unobservable: EXPSPACE-complete (Haslum & Jonsson, 1999)
  - partially observable: 2-EXP-complete (Rintanen, 2004)
- schematic operators:
  - usually adds one exponential level to PLANEx complexity
  - e. g., classical case EXPSPACE-complete (Erol et al., 1995)
- numerical state variables:
  - undecidable in most variations (Helmert, 2002)

Motivation

Background

of planning

More complexity results

- Background
- Complexity of planning
- More complexity results
- Summary

- Propositional planning is PSPACE-complete.
- The hardness proof is a polynomial reduction that translates an arbitrary polynomial-space DTM into a STRIPS task:
  - Configurations of the DTM are encoded by propositional variables.
  - Operators simulate transistions of the DTM.
  - The DTM accepts an input iff there is a plan for the corresponding STRIPS task.
- This implies that there is no polynomial algorithm for classical planning unless P=PSPACE.
- It also means that classical planning is not polynomially reducible to any problem in NP unless NP=PSPACE.
